Author's Declaration

I hereby declare that I am the sole author of this thesis. This is a true copy of the thesis, including any required final revisions, as accepted by my examiners.

I understand that my thesis may be made electronically available to the public.

Abstract

With "commercial and institutional buildings account[ing] for 12% of Canada's secondary energy use and 11% of [the] national greenhouse gas emissions" (National Resources Canada, 2014), the energy consumption of Canada's non-residential buildings plays a large role in both climate change and overall energy usage. Making these buildings more energy efficient provides opportunity to reduce both Canadian energy use and the overall effects of climate change from building construction and operation. The LEED New Construction v1 rating system stresses the importance of a building's energy efficiency by designating 25% of its points towards energy reduction opportunities providing clear indication of the CaGBC's belief in the potential for LEED certified buildings to reduce overall energy consumption in new buildings.

As LEED certified buildings have been constructed for over a decade in Canada, there are opportunities to assess how these buildings are performing from an energy perspective in comparison to provincial averages. This study looks at LEED certified academic buildings in Ontario and evaluates their energy intensity in comparison to provincial survey averages, broad public sector data made available by the Green Energy Act, campus-wide energy intensities, and additionally assesses their actual energy performance in comparison to the modelled energy results submitted for final LEED certification.

The results of this research show that the studied LEED certified academic buildings on average perform better than both their provincial average and campus-wide energy

iii

intensities. The energy modelled results provided for LEED certification on each building under-predicts the energy intensity of the building anywhere from 2 – 44%. Additionally, the results of this research demonstrate the need for better energy surveys and energy benchmarking practices across Ontario. The study aims to aid academic decision-makers in setting reasonable benchmarks for energy intensity targets and to provide recommendations for national benchmarking authorities, the CaGBC and USGBC, as well as energy modelling professionals.

Acknowledgements

Firstly, I would like to thank Professor Geoffrey Lewis for his on-going support, wisdom, amazing sense of humour, friendship, and endless guidance throughout this process. Without you my head would have exploded countless times and my experience at the University of Waterloo would not have been the same.

Secondly, a very large thank you to my committee member Professor Paul Parker for aiding in strengthening this research and pushing for more answers. A very large thank you to my reader, Dr. John Straube, for taking the time to go through my thesis and for providing constructive insight. Your knowledge and expertise on building performance has been highly regarded and discussed in our household for years. Thank you to all of the SEED faculty and my fellow SUSM colleagues for your broad knowledge, expertise and drive for a sustainable future. My depth of intellect has been significantly impacted by my time spent in the sustainability management program.

Thirdly, thank you to all of the contributors to my data collection (there are a lot of you). I could not have completed this research and case studies without all of the wisdom, expertise and data provided by countless energy professionals and academic institutions.

Lastly, thank you to the following people/groups/frivolities which made this thesis possible:

Chris Hadlock for your support, editing, and constant knowledge/input · My family for supporting me every step of the way with this thesis · University of Waterloo · Katherine MacLean for all of her hard work behind the scenes of the SUSM program · all forms of caffeine · CaGBC & USGBC · EQuest/EE4 · Microsoft Office · DropBox · Randy Van Straaten for your LEED and M&V help · my body & mind for making it through these past two years · MMM - specifically Antoni Paleshi, Victor Halder, & Arash Ghorayshi for your unparalleled knowledge · Holly Samuelson for your energy modeling expertise · study participants - Western University, McMaster University, Algonquin College & Lakehead University for the valuable information you provided · my Lenovo for surviving my thesis without avail · my friends and colleagues for trying to make this world better one research project at a time.

Dedication

I dedicate my thesis to the most important companions in my life: my husband Chris for his love, support, and understanding through these past two years; my family, friends, and extended family for their on-going support; and my lovable fur-babies – Casey and Bailey.

Without your endless support throughout this crazy journey this thesis wouldn't have been written and my thirst for knowledge quenched (for now...). May there be many more of these exciting turns in the future so that we can continue to grow and learn together.

Chapter 1: Introduction

1.1 Research Background

1.1.1 Defining Sustainability for Buildings

For the past 30 years the notion of sustainability has been discussed and debated worldwide. In the 1980s the characterization of the term "sustainability" really began to take form and in 1987 *Our Common Future,* more commonly known as *The Brundtland Report,* was released defining sustainable development [as] "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED, 1987, p. 41). With the world population increasing, as well as a rise in the population density of cities, the sustainable development of buildings became an important issue in the late 20th century. We now know the significance of buildings in the context of environmental impact, as "buildings generate up to 35 percent of all greenhouse gases, 35 percent of landfill waste, and 80 percent of all water consumed. It [is] clear that making buildings greener [can] have a significant impact on larger environmental goals" (CaGBC, 2013). From the 1980s to the late 1990s, there was no prescribed standard of what made a building sustainable (as distinct from more energy efficient) nor were there mandated construction practices which alleviated some of the environmental burdens associated with development.

In 1993 the U.S. Green Building Council (USGBC) was established by Rick Fedrizzi, David Gottfried, and Mike Italiano "to promote sustainability in the building and construction industry" (USGBC, 2014). Once the USGBC was formed, discussions with over sixty (60) firms and non-profit organizations surrounding a sustainable construction industry began and

ultimately led to the development of a new green building rating system. The Leadership in Energy and Environmental Design (LEED[®]) program was created by the USGBC in 2000 to precipitate change in the construction industry by providing guidance on how to implement green building practices, within the framework of a green rating system.

1.1.2 Canadian LEED Rating System

In the early 2000s, various US LEED rating systems were established for specific building types and different construction processes. In 2004, the "first LEED rating system adapted for Canadawide use was [launched,] the LEED Canada for New Construction and Major Renovations version 1.0" (CaGBC, 2010, p. xiv), abbreviated as LEED NC v1. The Canadian rating system, which was an adaptation of the US rating system, was changed to reflect Canada's climate, regulation, and building codes. LEED NC v1 will be used throughout this study as it is the mostoften used green rating system in the Canadian construction industry due to its applicability to almost all project-types seeking certification. The LEED NC v1 rating system allows owners, architects, engineers, and other building professionals to register their new buildings with the Canada Green Building Council (CaGBC) and throughout the design and construction process they can aim to achieve up to 70 LEED points in six (6) categories (see Table 1 below and Appendix A: LEED Rating System Categories and Points for a full listing of credits and categories). The more points the building attains, the higher its certification level and, in theory, the more sustainable the building.

Table 1: LEED Points Distribution Table

CREDIT CATEGORY	AVAILABLE POINTS	% OF POINTS
Sustainable Sites	14	20%
Water Efficiency	5	7%
Energy and Atmosphere	17	24%
(Optimize Energy Performance)	(10)	(14%)
Materials and Resources	14	20%
Indoor Environmental Quality	15	21%
Innovation in Design	5	7%
TOTAL	70	100% ¹

¹The sum total of the percentages for each credit category sums to 99% due to rounding.

A simple depiction of the entire LEED certification process for LEED NC v1 is shown in Figure 1 below. The first step is for the building owner and team to decide to pursue LEED certification in the early stages of the project. Throughout the design phase a pathway to achieve LEED is created and LEED credits are documented through both the construction documentation and construction phases. After construction is completed a final LEED submission package is sent to the CaGBC for review and auditing. Once the building has satisfactorily passed through the CaGBC audit LEED certification can be awarded to the building. Some credits, such as measurement and verification or thermal comfort, are evaluated for at least one (1) year post-occupancy.

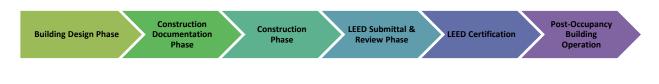

Figure 1: LEED Certification Process

1.1.3 Energy Efficiency

Starting with the energy crisis in the 1970s, energy has become a leading concern worldwide. In 1975 the province of Ontario released the first Ontario Building Code (OBC) to define the minimum construction and energy efficiency requirements of new buildings. "The purpose of the [OBC] is to set minimum standards for construction to minimize the risk to the health and safety of the occupants of a building and to provide for the barrier-free accessibility into a building and the energy efficiency of that building" (OBOA, 2014). Since the inception of the OBC in 1975 there have been five (5) new editions – 1983, 1986, 1990, 2006, and 2012. In each new edition of the OBC, the prescribed energy efficiency standards have become more stringent - greater amounts of insulation are prescribed in the roof, floor and walls of the new buildings, improved window performance, smaller window-to-wall ratios, higher mechanical equipment efficiencies, reduced lighting allowances, and more airtight construction. The impact of reducing building energy consumption is significant as "buildings [in developed countries such as Canada] account for 20-40% of total energy use. Besides the depletion of nonrenewable energy sources, this energy use contributes greenhouse gases to the atmosphere, with consequent detrimental effects" (Newsham et al., 2009, p. 897).

The LEED NC v1 rating system, aligned with the OBC, stresses the importance of a building's energy efficiency. Per the LEED Points Distribution Table (Table 1: LEED Points Distribution Table), approximately 25% (17 out of 70 points in the LEED NC v1 rating system) are in the energy and atmosphere category, of which energy optimization (energy modelling) is 14% of the total points. In the subsequent version of the rating system, LEED NC v2009, there is even more importance given to the energy and atmosphere category - 32% of the points, of which energy optimization is 17% of the total points. There is also the potential of earning even more energy points should the project decide to apply for innovation in design credits or regional priority credits attributed to energy savings. With "commercial and institutional buildings account[ing] for 12% of Canada's secondary energy use and 11% of [the] national greenhouse gas emissions" (National Resources Canada, 2014), the energy consumption of Canada's nonresidential buildings plays a large role in both climate change and overall energy usage. Making these buildings more energy efficient provides opportunity to reduce both Canadian energy use and the overall effects of climate change from building construction and operation. The USGBC and CaGBC decision that approximately 20-25% of the LEED rating system should be designated towards energy reduction opportunities provides clear indication of their belief in the potential for LEED certified buildings to reduce overall energy consumption in new buildings.

1.1.4 Documentation Practices for Building Energy Performance

In Ontario, the current practice in documenting energy efficiency compliance for both building code (OBC) and green rating systems falls to the energy modeller who creates computer simulations of the building based on either the design drawings (for building code compliance)

or the construction drawings and shop drawing submittals (for LEED compliance). These models reflect the intended building performance, not the actual 'as built' building performance. None of the current practices make it mandatory to complete a 'post-occupancy' energy model or update the model based on the actual energy use of the building post-construction (with the exception of the LEED M&V credit, EAc5). It is common knowledge that during the construction process alternative materials are used, designs are changed, and systems such as lighting or heating and ventilation equipment do not operate as they should due to less than perfect building commissioning and verification. All of these things can drastically change the energy consumption of a building and, were they incorporated in the model, would change the simulated model results, and the LEED points achieved, as well as the ability of a building to meet code. In other words, past and current LEED rating systems award points based on designed building operation, not actual building performance.

In order to meet the definition (and the intention) of sustainable development, actual building performance is what counts. Anticipated building performance as documented by energy models should not be the key metric for energy performance points or building code compliance – instead energy models should be used as a good preliminary estimate of how many LEED points a building could receive or give an indication of whether a building could meet building code. There should be some form of accountability after the building has been constructed to truly see how the building performs in its environment in order for a building rating to be a valid sustainability metric. Updating the energy model based on a post-occupancy analysis offers many advantages including helping the energy modeling professionals create

6

more accurate building simulations going forward, ensuring that LEED energy points are awarded for actual energy performance, and ensuring that a building's passing or failing grade for building code is justified.

1.1.5 Measuring Building Performance

To do a post-occupancy analysis of a building in order to determine the actual building performance, a process called measurement and verification (M&V) is used. Energy and water meters are added to the building to measure the actual amount of energy and water used. A single energy or water meter can suffice to determine the overall energy and water consumption of an entire building, but ideally separate meters are installed for different end uses such as lighting loads, plug loads, or process loads. By providing additional metering there is an enhanced ability to identify and troubleshoot potential building issues. If multiple meters are used, the data from these meters are typically uploaded to a server and analyzed by an M&V consultant on a regular basis – monthly, quarterly, or annually. The M&V consultant has the ability and responsibility to identify any possible issues in the building's performance. Single meter data can also provide some insight on how the building is performing, but the ability to identify to built in the building is significantly reduced.

The energy usage or energy intensity (energy per unit of floor area) data for a given building can be benchmarked by comparing them to energy performance databases, such as Natural Resources Canada and Statistics Canada's energy surveys. In the field of sustainability and energy efficiency consulting, it is common practice to compare post-occupancy data of new buildings to these energy surveys as a benchmarking procedure, though in academia this practice is frowned upon as the surveys provide energy intensity averages of the entire building stock and not equivalent (new) buildings. In this way, one can determine how a building is performing in comparison to other similar buildings in Canada. The M&V data can also be used to generate what is known as a calibrated simulation. A calibrated simulation is a computer model of the building that reflects actual weather conditions, building design, usage, mechanical schedules, lighting schedules and process loads. This type of simulation provides far more accurate results than a typical LEED energy model as real data (post-occupancy) are used to calibrate the model. With the calibrated simulation, energy conservation measures (ECMs) can be modeled to show the building owner how much energy or cost savings were (or could be) achieved by implementing different measures or by making slight changes to the building's current operating parameters.

1.2 Motivations

As a practitioner of sustainability and energy efficiency, I found a literature gap on the energy benefits associated with LEED certified buildings in Canada. It is particularly difficult to convince clients to pursue a green rating system that has no substantiated evidence of energy performance benefits and so I decided to assess the potential benefits for academic institutions to achieve LEED certification. Additionally, as a LEED practitioner, I have observed the disconnect between LEED certification during construction and actual building operation once the building has been handed over to the owners. There is a risk to the CaGBC and USGBC that,

8

if this disconnect continues, the current perception of LEED as a valid and advantageous green building label will become discredited.

LEED certified "buildings [are supposed to] create a healthier working environment for staff and tenants, through better air ventilation and more natural daylight. [They should] reduce waste, conserve energy, decrease water consumption, and drive innovation" (CaGBC, 2013). In order to ensure that these buildings are performing as they are intended, there need to be better metrics and processes in place to prove that there is, in fact, a measurable environmental benefit resulting from the LEED certification process. However, there seems to be a large divide between the benefit of energy efficiency and sustainability metrics associated with a building design and the actual operation and ownership of a building.

Green rating systems, such as LEED, provide sustainability benchmarks for buildings, but cannot be seen as absolute indicators of sustainability. "For many years it was commonly assumed that a LEED-certified building saved energy, though little performance data were available to confirm this assertion" (Scofield, 2013, p. 517). With the LEED Rating System having existed as part of building construction practices for over 10 years now, building data are available to determine how well these buildings are actually performing in comparison to other buildings. By analysing actual building energy data from various LEED certified buildings, more conclusive and evidence-based decisions can be made by clients to determine whether LEED sustainability metrics should be implemented into their designs.

9

The energy use of a building estimated during the design and construction phase for LEED certification and documentation does not accurately reflect the actual usage of a building postoccupancy. Unaware of the difference between a calibrated simulation and the LEED compliance simulation, building owners are likely to think that the energy consumption estimates documented for LEED credits EAp2 and EAc1 will be reflected in their actual consumption. However, evidence indicates this is not usually the case – the actual consumption is usually much higher than the simulation results and the savings in the energy models are comparisons to a baseline standard. Hence, there seems to be a misunderstanding of the predicted or modeled energy usage that results from a computer model during the LEED process – results that owners and operators then compare to actual consumption. One of the goals of this study is to identify the potential discrepancies between modeled energy use and actual energy use to raise awareness to the fact that there are usually large differences between the two (2) values.

While there is current academic literature on the energy performance of LEED certified buildings in the United States (Newsham et al. (2009); Scofield (2009); Kleinhenz et al. (2012); Menassa et al. (2012); Oates and Sullivan (2012); Scofield (2013)), there are current gaps in the knowledge surrounding building performance in both academic buildings as well as LEED certified buildings in Canada. Building type, geographical location, and climate play a role in the energy usage of buildings and a study within Ontario for academic buildings is needed so that universities and colleges can make educated decisions as to whether LEED certification is necessary or beneficial to meeting internal energy performance goals. For this reason, an additional goal of this study is to assess the performance of academic institutions in Ontario in order to help fill this knowledge gap.

1.3 Objectives

The main objective of this study is to determine the actual energy intensity of LEED certified academic buildings in Ontario and compare their energy performance to the average energy performance of Ontario academic buildings, current energy surveys, and modeled energy consumption. The results will aid academic institutions by identifying issues with the current energy benchmarking and LEED processes. Academic buildings were selected based on my experience in and with post-secondary buildings at various institutions across Ontario and as it was the largest classification of building types for universities and colleges. There have been many difficulties and issues faced by practitioners and occupants in this type of facility that need to be addressed through research. Some recommendations to remediate the issues identified in this research will be provided.

This objective will be achieved by answering the following questions:

- Do LEED certified academic buildings in Ontario have lower energy intensities than the average Ontario academic building?
- 2. Are government energy surveys and Broad Public Sector data useful tools as metrics of comparison for the energy intensity of academic buildings?

11

3. How accurate is the energy modelling for LEED certification in comparison to actual building energy usage?

By identifying issues within the current benchmarking and LEED certification processes it is the author's intention to provide recommendations to the Ministry of Energy, Natural Resources Canada and Statistics Canada, the CaGBC and USGBC, energy modellers, and academic decision makers.

1.4 Thesis Organization

The remainder of this thesis is organized into the following sections:

Chapter 2: Literature Review assesses, summarizes, and critiques previous studies and published documents that have been completed on similar topics related to this research.

Chapter 3: Methods discusses the data used in this research and the analysis methods used. It also discusses limitations to the study.

Chapter 4: Results and Discussion summarizes the results of the study and discusses the relevance, importance, and applicability of the analysis in detail.

Chapter 5: Conclusions and Recommendations present conclusions and next steps for further research.

Chapter 2: Literature Review

Academic institutions are increasingly faced with the decision as to whether or not they should utilize green rating systems, such as LEED, to guide the development and construction of new buildings on campus. The decision to pursue a green rating system is made through careful review of internal policies, institution goals, and marketing advantage. While there have been a number of studies (Newsham et al. (2009); Scofield (2009); Kleinhenz et al. (2012); Menassa et al. (2012); Oates and Sullivan (2012); Scofield (2013)) that have posed the question *how energy efficient are LEED certified buildings?*, the results are contradictory and are not specifically relevant to the geographic location, climatic conditions, and building types proposed in this research as all of these factors contribute to the energy usage of the associated buildings. As each of the aforementioned factors can have a great effect on energy use, this research aims to fill a knowledge gap by supplying decision makers at academic institutions in Ontario with new information that will allow meaningful decisions to be made in regards to the pursuit of LEED certification of their buildings.

This chapter summarizes previous academic research on the topic of energy performance of LEED certified buildings, discusses the current energy benchmarks available nationally, and reviews findings from previous research on the accuracy of building energy models.

2.1 Energy Performance of LEED Certified Buildings

Many buildings that have been designed and certified using the LEED NC v1 rating system have been occupied and in use for several years. Actual measured data from these buildings can be

13

used to determine if LEED buildings consume less energy than their non-LEED equivalents and national/regional averages. Over the past five (5) years, various researchers have published papers on their findings surrounding the actual building energy use of LEED certified buildings.

Newsham et al. (2009) re-examined data supplied by the New Buildings Institute (NBI) and US Green Building Council (USGBC) on 100 LEED certified commercial and institutional buildings located in the United States. Their findings showed that "on average, LEED buildings used 18-39% less energy per floor area than their conventional counterparts" (Newsham et al., 2009, p. 897). These results align well with the intent of the LEED rating system to lower building energy usage and therefore minimize carbon emissions. "However, [it was also concluded in this study that] 28-35% of LEED buildings [actually] used more energy than their conventional counterparts" (Newsham et al., 2009, p. 897) demonstrating that not all LEED certified buildings are high performance structures in operation.

Given the point structure of the LEED certification process, it is implied that the more LEED points a building achieves and the higher the level of certification (certified, silver, gold or platinum), the more sustainable the building. Newsham et al. (2009) found that "the measured energy performance of LEED buildings had little correlation with certification level of the building, or the number of energy credits achieved by the building at design time" (p. 897). This implies that the pursuit of higher levels of certification (usually at larger capital costs from personal experience) is not necessary in order to achieve better energy performance.

14

While one of the primary intents of the LEED rating system is to reduce energy use, the conclusions of this study illustrate that while the LEED rating system aims to provide more sustainable and energy efficient buildings, not all will be performing as desired. In general, the outlook seems positive in that LEED buildings were shown on average to use less energy than their non-LEED equivalents, yet in some specific cases the LEED buildings actually consumed far more energy. "While this might not be a problem for society, it is clearly a problem for the owner/operators of these individual buildings, who are not realising the energy performance that they (presumably) expected" (Newsham et al., 2009, p. 903) and also paid to achieve.

Scofield (2009) further analysed the study and results produced by Newsham et al. (2009) as well as the raw data provided by the NBI. While the results of Newsham's study showed that LEED certified buildings in general used less energy than their counterparts, Scofield (2009) points out that the Newsham's (2009) study only looked at on-site energy use, and not source energy. Source (or primary) energy includes off-site energy generation and transmission, which should be included when determining greenhouse gas (GHG) emissions associated with building operation. In order to get a true reflection of GHG emissions associated with building operation one would need to consider source energy use (Scofield, 2009).

Scofield's (2009) results, similar to those of Newsham et al. (2009), show that "LEED buildings use, on average, less site energy than comparable non-LEED buildings" (p. 1387) and finds that the energy savings amount to 10-17%. Yet, when "focusing on source energy, which accounts both for energy used on-site and the off-site losses associated with the generation and

distribution of electric energy, ... LEED certified commercial buildings, on average, show no significant primary energy savings over comparable non-LEED buildings" (Scofield, 2009, p. 1387). Scofield (2009) demonstrated that the overall energy savings of the LEED certified office buildings in Newsham et al.'s (2009) study could be minimized due to the source energy consumption calculation included in his study as well as using a different method to calculate the energy intensity of each building (equal weighting versus gross square footage method). The source energy calculations completed in his study utilized the US electric generation mix and distribution efficiency. Scofield's conclusions show that "LEED-certification, on average, is not lowering source energy consumption and, accordingly, is not delivering reduction in greenhouse gas emission associated with building operation" (Scofield, 2009, p. 1387). Scofield goes on to state that "[t]he majority of LEED-certified offices are using less energy (site or source) than comparable non-LEED offices (on an individual basis)... Collectively, however, because a relatively few large buildings dominate energy consumption, LEED offices (in total) are not using less energy (in particular, source energy) than their non-LEED counterparts" (Scofield, 2009, pg. 1390).

The difference between site and source energy use could have a large impact when performing a GHG emission analysis for building energy use, but for the sake of this thesis where decisionmaking for academic institutions is the focus, only energy usage at the building or campus level (i.e. site energy) will be considered. Additionally, this research analyses the energy usage of academic buildings located in Ontario and therefore would utilize the same or a relatively similar energy mix for all buildings studied. Upstream considerations, such as power generation fuel sources and transmission losses would also be useful in determining GHG emissions related to the energy usage of buildings and should be considered in future research in minimizing the impact of academic campuses on climate change.

In October 2008 the U.S. Department of the Navy imposed strict requirements that all new buildings constructed for the US Navy and the US Marine Corps obtain at least LEED Silver certification in order to satisfy Executive Order (EO) 13423. This order "mandates that all government departments reduce energy consumption by 30% by 2015" (Menassa et al., 2012, p. 46) when compared to baseline building performance per ASHRAE Standard 90.1-2004. Menassa et al. (2012) compared all 11 LEED-certified US Navy buildings with other Navy and Marine Corps "non-certified buildings of comparable size, usage, and location" (p. 46) as well as similar buildings from the Commercial Building Energy Consumption Survey (CBECS) database compiled by the United States Energy Information Administration of the Department of Energy. Their findings showed that "7 of 11 LEED-certified buildings have electric energy savings when compared to their non-LEED counterparts" (Menassa et al., 2012, p. 49). However, only 2 of the 11 buildings actually met the EO 13423 mandate of reducing energy consumption by 30% (Menassa et al., 2012). Furthermore, when comparing the LEED-certified US Navy buildings to the CBECS database, the findings showed "little to no savings, with a majority of the US [Navy] LEED-certified buildings consuming more electricity [per square foot] than the national average" (Menassa et al., 2012, p. 51). Menassa et al. (2012) pointed out that "the data shows that energy savings are not closely related to the number of points received in the Energy and Atmosphere section, [particularly EAp2 and EAc1] of the LEED certification process" (p. 52).

These results demonstrate that LEED certified US Navy buildings are not producing the desired energy savings when compared to similar US average building energy consumption.

Oates and Sullivan (2012) compared the energy consumption of 25 (out of the 53 total) LEED certified buildings in Arizona to both the national database (CBECS) as well as the energy model results documented for LEED certification. The "analysis of the LEED NC sample returned mixed results. On average, Arizona's LEED New Construction (NC) medium energy intense (MEI) buildings performed better than the national average [(13% more efficient),] yet worse [(4% less efficient)] than buildings located in similar climates" (Oates & Sullivan, 2012, p. 742). Furthermore, "Arizona's high energy intense (HEI) structures [laboratory spaces] performed considerably lower than national average [(35% less efficient)] and lower than buildings in similar climates [(12% worse)]" (Oates & Sullivan, 2012, p. 742). Again, the results of this study indicate that LEED certified buildings in Arizona are consuming more energy than similar buildings in the same climate and in some cases, consume more energy than the national average.

Kleinhenz et al. (2012) point out that other studies have shown that "15% of [the] LEED certified buildings [in the US] were actually performing in the bottom 30% of the comparable national building stock [(CBECS)] on an energy-per-sq-ft basis" (p. 28) and that "certified buildings are not living up to the label" (p. 28). As such, they decided to use their professional experience with various LEED certified projects in Ohio to determine why LEED certified buildings were underperforming in regards to energy efficiency. Their case studies indicated that many of the discrepancies were due to less efficient system designs and human error from the mechanical designers, energy modellers and LEED reviewers. The poor building performance often was due to "poor technical understanding or inattention by building owners and designers" (Kleinhenz et al., 2012, p. 28). Many designers tended to use old design practices with inefficient equipment or did not have adequate insight on how building mechanical systems actually work (Kleinhenz et al., 2012).

The "inefficienc[ies] outfoxi[ing] energy efficiency programs" (Kleinhenz et al., 2012, p. 29) such as LEED often stem from issues with the energy modellers and LEED reviewers on a project. Early versions of energy modelling software, such as EE4 (Natural Resources Canada, 2008), contained default plug loads for various space types which modellers tended to use rather than selecting values that more accurately reflected the actual building (Hadlock, personal communication, September 2013 – June 2015). "Building designers and energy modellers cannot rely solely on [reference guides and codes] and must use their own expert judgement [where] accurate energy modeling takes years of experience and advanced understanding of building energy systems and thermodynamics" (Kleinhenz et al., 2012, p. 29). Unfortunately, there are no minimum experience requirements for energy modellers documenting compliance for LEED certification and "it is virtually impossible for an organization, such as the USGBC [and the CaGBC], to fully inspect each energy model" (Kleinhenz et al., 2012, p. 29). Although third party reviews are part of the LEED certification process, it is virtually impossible to review all of the inputs to the model as the number of inputs is very large and model interactions are often complex. Furthermore, the achievement of LEED energy credits is determined strictly by the

performance of the energy model and not the actual performance of the building, meaning "measurement and verification is not required and nobody is held accountable for actually delivering promised energy savings" (Kleinhenz et al., 2012, p. 29). All of these factors certainly contribute to answering the question of why LEED certified buildings in the US are performing in the bottom 30% when compared to the national building stock as well as why poor energy efficiency projects are being rewarded with energy efficiency credits for LEED certification. Errors made during the modelling process can result in significant inflation of modelled savings. As a result, buildings with poor energy savings may still receive a large number of LEED energy points. An example of this would be a model where the fan schedule in the baseline case had the fans in the building running continuously whereas in reality they were only in use for an eight (8) to ten (10) hour period. Catching this mistake in a third-party review would reduce the overall energy savings results for the building by over 20%, with significant effects to the overall achievement of LEED points.

Scofield (2013) analyzed data from 953 office buildings in New York City (NYC), 21 of which were LEED certified, in order to determine how the energy performance of LEED-certified buildings compared to their non-LEED counterparts. Usually data from LEED-certified buildings are compared to the CBECS national database to draw an energy comparison, whereas this study used "NYC benchmarking data [with] measured data for hundreds of similar office buildings for the same year and geographical region" (Scofield, 2013, p. 519). NYC's local law 84 makes it mandatory for commercial building owners to upload their building energy data into ENERGY STAR's Portfolio Manager; it was these data that were used by Scofield. By comparing similar building spaces in the same geographical regions over the same period of time, the comparisons have higher validity due to very similar weather patterns (the same heating and cooling degree days). The study showed that "with regard to energy consumption and GHG emission the LEED-certified buildings, collectively, showed no savings as compared with non-LEED buildings. The subset of the LEED buildings certified at the *Gold* level outperformed other NYC office buildings by 20%. In contrast LEED *Silver* and *Certified* office buildings underperformed other NYC buildings" (Scofield, 2013, p. 517).

From the research reviewed here, there are mixed results when analysing the energy performance of both LEED certified and non-LEED certified buildings. Early studies (Newsham et al. (2009), Scofield (2009)) show that LEED certification correlates with slightly improved siteenergy performance, but also that some LEED certified buildings are actually performing worse than their non-LEED counterparts during operation and from a source-energy perspective. Recent study results (Scofield (2012), Oates & Sullivan (2012)) find that LEED certified buildings are not demonstrating increased energy efficiencies over similar non-LEED buildings. Additionally, the literature (Menassa et. al (2012), Oates & Sullivan (2012)) shows that there is little to no correlation between LEED certification level and overall buildings outperformance (with the exception of Scofield (2013) who found that LEED Gold buildings outperformed the national benchmarks while LEED Certified and Silver buildings performed worse). Kleinhenz et al. (2012) pointed out that many of the energy discrepancies of these buildings are due to less efficient system designs and human error from the mechanical designers, energy modellers and LEED reviewers.

2.2 Current Energy Benchmarks

All previous studies on LEED certified building energy performance have analysed building stock in the United States with most comparing their energy usage to the US CBECS. In Canada, Statistics Canada and Natural Resources Canada have been collecting national benchmarking data since 2000. Currently, there are five (5) relevant - both temporally and building type energy surveys that provide the average annual energy intensity values for various building usage types to compare against the energy usage of LEED certified academic buildings in Ontario.

In 2000, Natural Resources Canada and Statistics Canada collected the energy intensity of commercial and institutional buildings in Canada to create the Commercial and Institutional Building Energy Use Survey 2000 (CIBEUS 2000). "The survey involved collecting information on [the] building characteristics, occupancy characteristics, energy efficiency characteristics, [and the] energy consumption" (Natural Resources Canada, 2002, p. i) of 137,039 buildings nationwide. The results break down the energy intensity of the surveyed buildings based on various building characteristics such as geographic region, occupancy, and energy efficiency features. The intent of the survey was to "strengthen and expand Canada's commitment to energy efficiency in order to help address the challenges of climate change – by providing detailed information on the commercial sector that can be used to assess how well Canada is fulfilling its commitment to reducing greenhouse gas emissions" (Natural Resources Canada, 2002, p. i). The results showed that in 2000 the annual average site energy intensity for all educational buildings across Canada was 0.94 GJ/m². Ontario educational buildings performed

slightly better than the national average and were found to have an average annual energy intensity of 0.93 GJ/m². As this was the first energy survey of its kind in Canada, the energy intensities were aggregated and did not differentiate between specific academic building types. As mentioned in Chapter 1, the building type, geographical location, and climate play a role in the energy usage of buildings. An elementary school, high school and higher education facility will have very different occupancy, mechanical system schedules, and space types resulting in very different energy loads. Universities and colleges, for example, may have lab spaces that utilize powerful and high energy demand machinery whereas an elementary school would not. Ideally, national surveys and benchmarking tools should break out different academic space types to provide more appropriate metrics for academic institutions to use for decision-making.

In 2004, Natural Resources Canada and Statistics Canada completed the 2003 Consumption of Energy Survey for Universities, Colleges, and Hospitals (CES 2003). The survey's purpose "was to gather 2003 energy consumption data for universities, colleges and hospitals [nationwide.]The data gathered through this survey [would] deepen [the government's] understanding of the various aspects of energy consumption in these sectors" (Natural Resources Canada, 2005, p. 1). The CES 2003 survey assessed and analysed energy data from 123 university campuses, 228 college campuses and 729 hospital complexes. The results of the survey were broken down by building sector and energy source as well as region and can be used "to calculate energy intensity for energy use per square metre, per student or per bed" (Natural Resources Canada, 2005, p. 2) as well as to provide a snapshot of the national and provincial energy intensity averages for academic institutions and hospitals at that time. The results of this survey showed that the average energy intensity in Canada was 2.04 GJ/m² for universities and 1.48 GJ/m² for colleges. Regionally, the energy intensity in Ontario was 2.19 GJ/m² for universities and 1.35 GJ/m² for colleges. The results of the CES 2003 study provided a more accurate comparison for the energy intensities of universities and colleges over the previous CIBEUS 2000, due to the aggregation of all academic institution types in CIBEUS.

In 2007 Natural Resources Canada and Statistics Canada completed the 2005 Commercial and Institutional Consumption of Energy Survey (CICES 2005) which surveyed 440,863 commercial and institutional buildings across Canada. The CICES 2005 study had a "scope [that] was increased to cover a much broader cross section of the commercial and institutional sector" (Natural Resources Canada, 2007, p. 2) than the previous CES survey. "This [CICES 2005] survey gathered data on the energy consumption and energy intensity of businesses and institutions...[as well as the] age of the establishments; the energy sources used for space heating, space cooling and water heating; establishment spending on energy consumption; and the use of auxiliary equipment" (Natural Resources Canada, 2007, p. 5). The results of this study provided the energy consumption and energy use intensities per sector, by region, by energy source, floor area, and establishment age. The energy intensity in Canada was found to be 1.42 GJ/m² for community colleges and CEGEPs (pre-university colleges in Quebec), and 2.59 GJ/m^2 for universities. In Ontario the energy intensity was found to be 1.55 GJ/m^2 for community colleges, and 3.12 GJ/m^2 for universities. It is interesting to note that the average energy intensity for academic institutional buildings is higher in 2005 than in the previous studies (2000 and 2003). This elevation in energy intensity may be due to actual energy usage

increasing or different survey methods being used by NRCan and Statistics Canada. No information could be found to determine the actual reasoning and NRCan did not respond for comment.

The 2008 Commercial & Institutional Consumption of Energy Survey (CICES 2008) was completed by Statistics Canada and Natural Resources Canada to "improve [the Government of Canada's] understanding on how and where energy is used, which in turn helps to identify energy efficiency opportunities and progress towards a more energy efficient economy" (Natural Resources Canada, 2011, p. I). In 2008 Statistics Canada surveyed 469,118 establishments for their building type, floor area, energy consumption, energy intensity, building age, and energy sources used for various types of heating and cooling. The CICES 2008 survey found that the energy intensity of community colleges and CEGEPs in Canada was 1.32 GJ/m^2 and universities 1.70 GJ/m^2 . When analysed by region, community colleges in Ontario had an energy intensity of 0.95 GJ/m^2 while universities in Ontario averaged 1.24 GJ/m^2 . The results of this study showed drastic improvements in building energy performance in 2008 when compared to previous studies conducted nationally. It was not stated why such drastic improvements were demonstrated, but one (1) assumption that can be made is that these savings were attributed to government, independent electricity system operator (IESO), power authority and public utility energy incentives (such as the High Performance New Construction (HPNC) or the Feed-in-Tariff (FIT) programs) for building retrofits and new buildings being constructed with more energy efficient equipment. Some additional improvements in the

survey results may be due to changes in survey method and larger sample sizes, but no additional information could be confirmed by NRCan.

The most recent survey completed by Statistics Canada and Natural Resources Canada was the Survey of Commercial and Institutional Energy Use – Buildings 2009 (SCIEU 2009) completed in 2012. The SCIEU 2009 collected energy results from 482,266 commercial and institutional buildings nationwide. "The objective of the building-based component of the SCIEU [was] to establish baseline energy consumption figures against which new policies and programs geared toward energy efficiency in [commercial and institutional] buildings [could] be measured" (Natural Resources Canada, 2012, p. I). It is important to note that in the SCIEU 2009 both colleges and universities were aggregated into the 'other' building category which also included entertainment, leisure and recreation buildings (arenas), as well as shopping centres. The results showed that buildings categorized as 'other' in Canada had an energy intensity of 1.01 GJ/m². Regionally, in the Great Lakes climate zone, which includes Ontario, the buildings in the 'other' category had an energy intensity of 0.97 GJ/m². The results of this 2009 assessment would therefore not accurately reflect the energy use intensity values specific to colleges and universities as they are aggregated with other building types.

The Ontario Green Energy Act was created in 2009 "to expand renewable energy generation, encourage energy conservation and promote the creation of clean energy jobs" (Ministry of Energy, 2015). In 2012, *Regulation 397/11 Energy Conservation and Demand Management Plans* under the Green Energy Act was enforced which mandated that all "public agencies,

starting in July 1, 2013, [had] to report annually to the Ministry of Energy on their energy use and greenhouse gas (GHG) emissions and publish the reports on their websites" (Ministry of Energy, 2015). The public agencies in Ontario required to provide annual reporting includes facilities such as colleges and universities. The data (BPS 2012) provided by all public agencies are published by the Ministry of Energy on their Energy use and greenhouse gas emissions for the Broader Public Sector webpage. This publicly available data provides valuable insight into how universities and colleges in Ontario are performing from an energy intensity perspective. From the BPS 2012 data, the university and college buildings throughout Ontario were assessed to determine the average energy intensities. First the BPS 2012 data were filtered by sector name "post-secondary educational institute" which listed only universities and colleges. The data was then sorted and separated by subsector name "university" or "college". A review of the data was completed and easily identifiable incorrect entries were removed from the data set (i.e., duplicates, negative energy, extremely excessive/impossible energy values). All of the reported values for energy consumption sources (electricity, natural gas, fuel oil 1 & 2, fuel oil 4 & 6, propane, coal, wood, district heating, and district cooling) were converted from their reported units into GJ and then summed to determine the total energy used. The total energy consumption of the university buildings was divided by the total GFA of the university buildings, and similarly the total energy consumption of the college buildings was divided by the total GFA of the college buildings. The calculated average energy intensity of colleges and universities was found to be 1.49 GJ/m² (1.65 GJ/m² for universities and 1.15 GJ/m² for colleges).

Over the course of a decade the Government of Canada, through both Natural Resources Canada and Statistics Canada, has played a large role in researching the energy usage of its commercial and institutional building stock. The five (5) surveys that were completed provide an indication of how the average building (for various building types) in Canada was performing from an energy perspective. The variation in energy intensity values and aggregation categories provided by each government study does hint at the complexity associated with accurately quantifying building energy. This is yet another reason why additional studies, such as this one, can help provide insight where information is lacking specificity. Additionally, the publicly available energy data published due to the Green Energy Act provides another possible standard of comparison for universities and colleges to assess their buildings against.

2.3 The Accuracy of Building Energy Models

To identify the discrepancies between actual building energy consumption and energy consumption predicted by energy models, previous research on the accuracy of building energy models is reviewed and summarized in this section.

With elevated energy prices and an increased awareness of energy uses, the field of energy simulation has radically increased in the past decade (Ahmad & Culp, 2006). "Today energy codes and green building standards promote the widespread use of building energy simulation during the building design" (Samuelson et al., 2014, p. 1). These simulations (energy models) are used to demonstrate compliance with prerequisites and/or credits in green building standards, such as LEED, as well as for Ontario Building Code compliance. Energy models are

used in comparison against baseline standards rather than providing an absolute prediction of the building's energy consumption (Samuelson et al, 2014), as the project-specific models that are generated are generally poor predictors of the actual energy usage of buildings (Turner & Frankel, 2008).

Several studies (Ahmad & Culp, 2006; Turner & Frankel, 2008; Stoppel & Leite, 2013; Samuelson et al., 2014) have found that, on average, there are large discrepancies between actual building performance and design model results. The predicted energy use intensities (EUI) for the simulated buildings in these studies were found to deviate from the actual measured energy use intensities by large amounts, ranging from 14% to 41%. "The comparisons between modeled and actual consumption can be complicated for several reasons: the building as actually built can differ dramatically from the one modeled at the design stage" (Diamond, 2011, p. 8); there can be differences in occupancy patterns, number or type of installed equipment (notably laboratory equipment or computers), lack of proper commissioning, usage change, or even poor initial modeling. Further analysis by Stoppel & Frankel (2013) point out that the larger discrepancies between actual energy use and predicted energy modelling results appear when over-estimating heating energy, building occupancy, and daily water consumption. All of these factors can "make this comparison [between modeled and actual consumption] difficult to interpret" (Diamond, 2011, p. 8).

"The LEED program[, in particular,] awards energy performance points [for LEED credits EAp2 and EAc1] on the basis of predicted energy cost savings [of only regulated energy loads]

compared to a modeled code baseline building" (Turner & Frankel, 2008, p. 3). The "nonregulated loads including plug loads, exterior lighting, garage ventilation, elevators (vertical transportation), and process loads" (CaGBC, 2004, p. 177) were not included in the proposed or reference building for a LEED v1 energy model nor were they captured in the energy savings calculations. The resulting difference between actual and modeled energy performance could be significant in the calculation of LEED points. To put this into perspective, on a LEED v1 project, one (1) point is awarded for every 5% of energy savings when compared to the ASHRAE 90.1-1999 baselines. If researchers are seeing deviations between actual and modeled energy results between 14% and 41% for a LEED v1 project, then buildings could be either losing or falsely achieving anywhere from 3 to 8 LEED points based on these discrepancies (assuming the baseline model is accurate). This large deviation in number of points could make the difference between achieving and not achieving LEED certification or reaching a higher level of certification. It is also important to note that the LEED energy credits EAp2 and EAc1 "are awarded based on simulated cost of only the regulated energy components, not the wholebuilding energy cost [and therefore] modeled results must be interpreted with care when comparing them to actual energy bills" (Diamond, 2011, p. 4).

"As energy prices increase, the interest in saving energy has [also] increased. Simulation provides a mechanism to determine where savings opportunities exist or energy inefficiency occurs in a building" (Ahmad & Culp, 2006, p. 1142). As such, academic institutions have taken a keen interest in determining how to implement energy savings on campus by performing energy audits and determining energy conservation measures (ECMs) that could be

implemented. Ahmad and Culp's (2006) analysis looking at energy simulation results of academic buildings in 1999 and 2004 in the United States found discrepancies between predicted energy usage and actual building energy usage of $\pm 30\%$. Even more alarming, when looking at individual building components, such as chilled water or hot water, discrepancies exceeding $\pm 90\%$ were found (Ahmad & Culp, 2006).

By including a calibration step in energy modelling, where the modeling process "included inputting actual weather data, adding unregulated loads, revising process loads (often with submetered data), and updating a minimal number of other inputs" (Samuelson et al., 2014, p. 1) the deviation from actual measured energy use can be reduced to a conservative 7% underprediction (Samuelson et al., 2014). The majority of the discrepancy between the predicted energy usage and actual energy usage was corrected when process loads were updated, missing unregulated loads were added, and the actual weather data were included in the energy models (Samuelson et al., 2014).

Previous published research on the accuracy of energy modelling has analyzed LEED NC v1 energy models and techniques. It is important to note that although process loads were not required to be accounted for in the v1 LEED energy models, newer versions of LEED (Version 2009 and the newest Version 4) do take into account process loads, likely reducing the difference between modeled and actual energy consumption.

In summary, the current academic literature demonstrates that LEED certified buildings can demonstrate improved energy performance when only site energy is analyzed, but the savings demonstrated have been minimal. Additionally, there is little support to demonstrate that higher levels of LEED certification lead to better overall building energy performance. Energy practitioners (Kleinhenz et al. (2012)) found that many of the errors stem from human error in the design, construction, energy modelling, and building operation processes. Study results varied depending on the type of building, geographical location, and the benchmark used to draw the comparison. While many LEED-certified buildings are performing better than the CBECS building stock in the United States, there is little research to show how LEED certified buildings are performing in comparison to the Canadian building energy intensity averages for specific building types and geographical locations. There is a need for building-type specific comparisons in different geographical locations in order for new buildings to set realistic and sustainable energy targets.

Five (5) national surveys on commercial and institutional energy usage have been completed by Natural Resources Canada and Statistic Canada over the past decade. These five (5) studies provide average building energy intensity data to assess how academic institutions are performing from an energy perspective. Given that each of the studies have different aggregating categories, some are more relevant than others for particular building types. Additionally, the published broad public sector data made available by the Green Energy Act can also be used for comparison by academic institutions. This will be discussed further in Chapter 4.

Existing literature on energy modelling has shown that energy models are poor predictors of the actual energy usage of buildings due to modelling inaccuracies. On average there are discrepancies between actual and modeled energy usage ranging from 14% to 41% due to various circumstances. The poor predictions of energy models can be improved through the experience of the energy modeller, using M&V data from a building and performing a calibrated simulation.

The outcome of this literature review demonstrates that there are contradictory results as to whether or not LEED certified buildings are more energy efficient than their non-LEED counterparts. While the previous research demonstrates that US LEED certified buildings do on average perform slightly better from a site energy perspective than US national benchmarking data, previous studies are not applicable to the geographic location, climatic conditions, and building types proposed in this research. As each of the aforementioned factors can have an effect on energy use, this research aims to fill a knowledge gap by supplying decision makers at academic institutions in Ontario with new information that will allow meaningful decisions to be made in regards to the pursuit of LEED certification on their buildings.

Chapter 3: Methods

In this chapter the methods used for conducting this study will be discussed. This includes an overview of the case study approach as well as the criteria methods used to select the appropriate research data.

3.1 Case Study Approach

Case studies were used for this research as "the case study is the most flexible of all research designs, allowing the researcher to retain the holistic characteristics of real-life events while investigating empirical events" (Schell, 1992, p. 2). It allows researchers to "investigate[] a contemporary phenomenon within its real-life context when the boundaries between phenomenon and context are not clearly evident and in which multiple sources of evidence are used" (Yin, 1984, p. 23). When studying building performance, it is impossible to remove a structure from its physical boundaries and purpose as a functioning facility and, as such, buildings need to be studied within the context of their intended purpose, location, and operating conditions.

This research analyzes measurement and verification data from LEED certified academic buildings located in Ontario. For each building, these data were compared with modeled (predicted) performance, to provincial average building energy intensities set forth by the Natural Resources Canada and Statistics Canada energy surveys, average energy intensities from the BPS 2012 data, and to campus-specific energy intensities. Utility data, campus energy

data and the energy simulation results for each of the buildings participating in this study were obtained directly from the owners and operators of each of the academic institutions.

3.2 Data and Selection Criteria

The CaGBC maintains a directory of project profiles on their website which allows professionals to view buildings that have either been LEED certified or are in the process of obtaining certification. The CaGBC database was used to select several similar LEED certified buildings for comparison purposes. It should be noted that in order to perform an "apples-to-apples" comparison of energy consumption across various buildings, certain key variables, known to have a large impact on energy consumption, must be consistent from one (1) building to the next. Those key variables were: climatic region, building size, building type, and occupancy schedule. By selecting buildings whose key variables are similar, fair comparisons can be made; additionally, this process provides an opportunity to draw conclusions based on other outside factors such as occupancy patterns, mechanical schedules, lighting loads, and process loads.

Figure 2 (below) is a conceptual flowchart summarizing the data selection process used for this study. Each step is discussed in detail below.

Figure 2: Flowchart Summarizing Data Selection process

As of February 2015, the CaGBC's project profile directory lists 1,840 buildings in Ontario. As this study aims to assess the energy efficiency of LEED certified academic buildings, the results were filtered to only include buildings with owner type "University/College", reducing the total number of potential research candidates to 112. Buildings that have already obtained LEED certification are of interest in this research as post-occupancy operational data should be accessible for some of these buildings. By using this selection criterion 59 of the possible 112 buildings were eligible – with the rest having been registered with the CaGBC but still under construction or currently going through the certification process.

It is important to select a specific project type to ensure a fair comparison between buildings as the energy usage of different types of academic spaces will greatly differ. For example, academic laboratories have significantly different hourly schedules, much higher water and energy loads for equipment and very different occupancy than a typical lecture hall/ classroom type structure. Of particular interest to the author, due to professional and educational experiences, were *'lecture* hall/classroom' building types that fall under the "University/College" owner group. Additionally, the 'lecture hall/classroom' category has the largest number of LEED certified academic buildings (25 out of 59) in the "University/College" grouping. This classification reflects typical mixed-use academic buildings in which there would be staff offices, student work spaces, as well as lecture halls/theatres for student learning. Other academic buildings certified that fell into the 'University/College" ownership category included spaces like libraries, sports facilities, hospitals/clinics, residences, community centres, and laboratory spaces which would have varying process loads and very different schedules for each building. To minimize the energy usage differences due to building use type, the 'lecture hall/classroom' category was selected and a total of 25 buildings (out of the 59 LEED certified buildings) were assessed.

For each building certified with the CaGBC a project profile and LEED Scorecard is created. The profile describes key features of the building, whereas the scorecard provides a breakdown of the credits achieved for LEED certification. Examples of project profiles and LEED Scorecards are provided in Appendix B: CaGBC Project Profiles, LEED Scorecards, and CaGBC Building Selection Table. Each of the project profiles and LEED Scorecards for the 25 'lecture hall/classroom'

buildings were reviewed to determine which had achieved the LEED M&V credit EAc5. The intent of the LEED M&V credit is to "provide for the accountability and optimization of building energy and water consumption performance over time" (CaGBC, 2004, p. 242). Metering equipment must therefore be installed to measure various energy end uses including: lighting systems and controls, motor loads, variable frequency drive operation, chiller energy, cooling loads, boiler energy, economizing control, air and ventilation equipment energy, process energy systems, water use, and irrigation systems (CaGBC, 2004, p. 242). Another requirement for the LEED M&V credit is that an M&V plan following the International Performance Measurement and Verification Protocol Volume 1 (IPMVP) options B, C or D must be created, requiring the M&V consultant to monitor the aforementioned building loads for at least one (1) year postoccupancy. This monitoring process aids in identifying and remediating any performance issues that may be occurring in the building, with the goal of reducing the building's water and energy use to the designed/intended performance goals. Selecting projects that have achieved the LEED M&V credit should have ensured (which was not always the case) that energy data for at least a one (1) year period after LEED certification were readily accessible. Ideally, the information presented in the M&V reports could be utilized in this research.

After careful review of the CaGBC project profiles, it was determined that 10 of the 25 buildings achieved the LEED EAc5 credit. Upon further analysis, one (1) of the ten (10) buildings had been certified in December 2014 and would therefore not have a full year of post-occupancy energy data available for this research. This building was therefore removed from consideration. After this selection criterion was applied, nine (9) possible buildings were available for assessment. A table showing the potential buildings for use in this study with selection criteria is shown in Appendix B: CaGBC Project Profiles, LEED Scorecards, and CaGBC Building Selection Table.

Lastly, this study aims to analyze the energy usage of academic buildings within close proximity to one another, as geographical and climatic differences can impact the energy performance of a building depending on the building type. Buildings located in Ontario were selected to minimize the impact of weather differences. Additionally, the average heating degree days (HDD) and cooling degree days (CDD) over a five (5) year period for each of the proposed locations were compared to ensure that the proposed buildings had similar weather conditions. It should be noted that the weather in Sudbury, Ontario was considerably different (approximately 800 more HDD and 110 less CDD than the average of the nine (9) buildings) than southern Ontario where the other eight (8) academic buildings were located and that this could lead to elevated energy usage. In order to evaluate potential differences in energy usage between northern and southern Ontario, the energy intensities for both northern and southern Ontario academic institutions were created and compared. The results from this analysis were contrary to what was expected – the energy intensity of the northern academic institutions was less than (1.02 GJ/m²) that of the southern academic institutions (1.23 GJ/m²). Upon further assessment, these results could be skewed due to low participation in the northern province as the reporting was not mandated until 2013 and poor data quality (numerous entries for northern Ontario were missing or out of the ordinary). After discussions with energy professionals, they would expect to see larger energy intensities in the northern climates. This assessment, unfortunately, provided inconclusive evidence as to how much the energy intensity

would differ between warmer and cooler climates in Ontario and the affect it may have on the results of this research.

Owners of the nine (9) candidate buildings were contacted via email and telephone to determine their interest in participating in this research. They were asked if they were willing to provide the completed LEED EAc1 letter template, any M&V reports, campus-wide energy usage data, and building specific energy usage data for a one (1) year period after the building achieved LEED certification. Considerable effort went into convincing building owners to participate in this research. Two (2) of the building owners did not respond after countless emails and phone calls. One (1) building owner could not provide the data requested because after three (3) years of certification their M&V data was still reporting incorrectly and therefore information on the building's energy usage could not be quantified. Another building owner hesitated to provide the data requested because they felt it would require too much effort on their behalf to find the LEED records and additionally felt that it would most likely cost money to get the information from their LEED consultants. After significant consultation, they provided the information requested and participated in this research. As a practitioner in this field of sustainability and energy efficiency, there seems to be a negative stigma associated with the process of LEED certification and, as such, it was difficult to convince owners to participate in this research. Much of the data collected were a result of professional ties within industry and the provision of aid to owners in providing the information requested.

Of the nine (9) buildings eligible for the research, only four (4) academic institutions – McMaster University in Hamilton, Lakehead University in Orillia, Western University in London, and Algonquin College in Ottawa - responded favourably and could provide the requested information. As Western University had two (2) eligible buildings take part in the research, a total of five (5) buildings comprised the study, as shown in Table 2 below:

Academic Institution	Building	Location	Size (m²)	Certification Level	Usage Type
Western University	Claudette MacKay- Lassonde Pavilion	London, ON	3703	Gold	Lecture hall, offices, lab spaces, common use spaces
	Stevenson Lawson Hall	London, ON	11714	Silver	Offices, classrooms, common use spaces
Lakehead University (Orillia Campus)	Simcoe Hall	Orillia, ON	6083	Platinum	Classrooms, lecture halls, lab spaces, office spaces
McMaster University	Ron Joyce Centre	Burlington, ON	9624	Gold	Classrooms, lecture halls, meeting rooms, auditorium
Algonquin College	Algonquin Centre for Construction Excellence (ACCE)	Ottawa, ON	18460	Platinum	Lab spaces, transportation hub, lecture halls, cafeteria, workshops, offices

Table 2: Buildings Selected for Research

Each of the buildings, although all listed as "lecture hall/classrooms" type, have very different mixes of building use. In order to identify potential differences between the buildings studied an estimated breakdown of the floor area attributed to different space types was requested from each building owner. Four (4) of the building owners provided estimates of the floor area

breakdowns (these estimates do not completely agree with the documented floor areas noted in Table 2). A summary of each building is shown in Table 3 below.

Academic Institution	Building	Classroom (m ²)	Lab (m²)	Offices (m ²)	Common Use (m²)	Other (m²)
	Claudette

Table 3: Space Type Areas (and percentage of GFA) for Case Study Buildings

With the M&V data in-hand for the five (5) participating buildings, the annual energy usage and energy intensity of each building could be calculated. The data from the M&V reports from each university were used to calculate the annual energy consumption (by energy source) for each building. The annual consumption for electricity, natural gas, chilled water, and steam was calculated and converted to gigajoules (GJ) to allow for building-to-building and building-tobenchmark comparisons. The total annual energy usage for each building was then determined by summing the total GJs for each energy source. It should be noted that the data from the M&V reports was specific to site energy only; source energy, such as the energy utilized to create steam and chilled water at the central plant (applicable to the Western University buildings), are not captured in this research as there was insufficient information to do so.

After determining the actual annual energy consumption for each building, the energy intensities for each building were calculated by dividing the total building energy (in this case annual energy usage in GJ) by the building's gross floor area (GFA). It should be noted that the data provided for the Algonquin College ACCE building was presented by the owners in the form of an energy intensity value in equivalent kilowatt hours per square foot (ekWh/ft²). This means that the building owners provided one (1) energy value for their building by converting the energy usage for both electricity and gas consumption of the ACCE into kWh and dividing it by the area of the building instead of providing separate energy end use loads. The provided energy intensity value was then converted from ekWh/ft² to GJ/m².

The calculated building-specific energy intensity could then be compared to both the average provincial energy intensity set forth by Natural Resources Canada and Statistics Canada, and the campus-specific energy intensities. The intent is that the comparisons between the provincial average energy intensities, BPS 2012 data, and campus-specific energy intensities should provide an indication of how LEED certified academic buildings within the same region are performing in comparison to other academic buildings.

The average annual energy intensity for each campus was either provided directly by the universities/colleges studied or determined from the "Energy use and greenhouse gas

emissions for the Broader Public Sector" (BPS 2012) spreadsheet published by the Ministry of Energy. This BPS 2012 spreadsheet includes the annual energy usage categorized by energy source for public buildings in Ontario as mandated by the Green Energy Act, 2009. The campuswide energy intensities (by energy source) for McMaster University and Lakehead University were determined using the information presented in the BPS 2012 document. The energy consumed by each energy source was converted to GJ and then the energy intensity was calculated by dividing the GJ by the total campus GFA. Similarly, Western University provided their raw BPS 2012 data which was then converted to GJ. The energy intensity was calculated by dividing the total annual energy in GJ by Western University's total campus GFA.

As an additional outcome of the research, this study aims to identify discrepancies between the LEED energy model results documented in the LEED EAc1 letter templates and the measured actual building energy usage. Energy usage depends greatly on a large number of variables, including quantity of occupants as well as building schedules - the hours that the building remains open and in use. What is presented in the energy model is information presented by the owner, architect and designers in the construction drawings and shop drawings for the project. The energy modeller is responsible for trying to accurately simulate how this building will be operated to determine anticipated energy usage. With any energy model, there is possibility for the energy modeller's assumptions to be erroneous due to unknown changes to the building usage, changes to the occupancy, or misinformation presented by the design team in regards to building envelope, mechanical and electrical systems. Ideally, there should not be large variances between the predicted modeled energy consumption and actual building energy

usage; however, numerous studies have shown that there usually are, as described in the literature review. The magnitude of the discrepancies found in this research will be identified and recommendations to the CaGBC and USGBC, as well as LEED energy modellers will be provided based on the results from the analysis.

3.3 Limitations

Limitations remain in this study despite the many efforts made to reduce them. For example, this research compares building-specific energy intensities to the university and college average energy intensities presented in Natural Resource Canada and Statistics Canada's national and provincial energy surveys (CIBEUS 2000, CES 2003, CICES 2005, CICES 2008, and SCIEU 2009). Since the Statistics Canada data are averaged by province (with the exception of SCIEU 2009), the comparison will only provide an estimate of how academic buildings in a specific region of Ontario are performing in comparison to energy intensity averages for all of Ontario. The validity of the comparison is somewhat weakened due to the fact that the benchmarks do not have location specific data. A better "apples-to-apples" comparison would compare the data set to non-LEED equivalent buildings of similar vintage in the same towns or regions. Efforts have been made to provide comparisons between campus-specific and building-specific energy intensities to increase validity.

An analysis was completed using the BPS 2012 data with the intention to demonstrate the energy intensity differences between northern and southern Ontario, but the results demonstrated were not considered to be normal due to low participation and poor data

quality. Ratio based weather normalization of the HDD could have been used to normalize the effect of climate on energy data. This type of weather normalization divides the total energy consumption (or energy intensity) by the number of HDD. Unfortunately, this type of normalization does not provide an accurate basis for comparison as only a portion of the total building energy usage is dependent on weather. In order to accurately normalize for weather, sub-metering would be required for end uses such as lighting, plug loads, and process loads (any loads that are not dependent on weather) in order to calculate the fraction of the total energy used for heating. The heating energy for each building would be divided by the total HDD and then the non-heating/non-weather dependent end uses would be analyzed separately. This level of detail in building data is not provided in the provincial benchmarks by NRCan and Statistics Canada nor the BPS data.

To further demonstrate the variability between normalizing by HDD using the ratio based and weather dependent methods, both quantities were calculated and compared. Ratio based normalization was completed on all five (5) case study buildings and the weather dependent method was completed on four (4) of the buildings (the ACCE did not provide energy source data). The weather dependent consumption method results ranged from 7% to 60% of the values obtained in the ratio based normalization method demonstrating that in most of the buildings the energy required for heating is much lower than the base loads.

Additionally, the aim of this study is not to compare the buildings to one another, but to compare the case study buildings to the provincial average, which does not take into account HDD.

As this study only compares LEED certified university and college buildings with "lecture hall/classroom" designation located in Ontario, and several owners declined to participate in this study, the sample size for this work was small and of unknown representativeness. Further studies would need to be completed for other geographical regions and building usage types as these variables could lead to different energy usage results, and may not be comparable to lecture/classroom buildings. Additionally, the goal of this research was to determine whether LEED certified academic buildings perform better from an energy perspective than their non-LEED counterparts. As only five (5) buildings took part in the study there was not enough data to draw such specific conclusions. As more buildings achieve certification and can provide M&V data, additional buildings can be compared to answer the question with more certainty, as long as data are also available from equivalent type and vintage non-LEED buildings.

From a temporal perspective, these buildings presented annual energy usage data from varying years. Discrepancies between annual weather data could affect the energy usage of a building as there would be different heating and cooling loads associated. Normalizing by HDD and CDD is a possibility if you were comparing each of the buildings to one another, but, again, in this research the author is comparing the buildings to available provincial average energy intensities

which do not provide data that could be normalized. Ideally the utility and water usage data from all of the buildings in the data set would be for the same time period.

This research only assesses LEED NC v1 buildings (and the associated modeling guidelines) to quantify the difference between the model predicted energy data and the actual energy data. Changes have been made to the modeling guidelines in the LEED Reference Guide v2009 (which followed LEED v1) that have made it mandatory for energy models to include an estimate for process loads – something that was not required in LEED NC v1. Therefore, energy modelled results for energy usage should be more reflective of actual energy usage in LEED NC Version 2009 and LEED NC Version 4 (to be released in Canada in 2016) than for LEED NC v1 buildings.

This study will provide recommendations for reducing the discrepancies between energy modelled results and actual building usage based on the results of this study and the author's experience as a LEED practitioner. The recommendations will focus on the modeling process in general and will not go into specific details for each the five (5) case study buildings (as a calibrated simulation or M&V report would).

Due to the scope of this research - comparing actual energy intensity of buildings to provincial energy intensity averages as well as to the modelled energy intensity - life cycle emissions associated with energy use will not be calculated. It would be interesting in future research to investigate both the site and source level energy usage of these LEED certified buildings.

Chapter 4: Results & Discussion

Using the methods and techniques described in Chapter 3, the M&V data as well as the modeled energy use from McMaster University, Western University, Lakehead University, and Algonquin College were evaluated and compared to the existing Canadian energy surveys and campus-wide energy intensities. The results of each of these comparisons are discussed below.

4.1 Annual Building Energy Consumption and Energy Intensity

Energy use by source, total energy consumption, GFA, and the energy intensity of each building included in this study are summarized in Table 4 below.

	Building					
	Claudette MacKay Lassonde Pavilion	Stevenson-Lawson Hall	Simcoe Hall	Ron Joyce Centre	ACCE	
Electricity (GJ)	4673	6768	6826	3855	-	
Natural Gas (GJ)	0	0	527	2211	-	
Chilled Water (GJ)	794	1686	0	0	-	
Steam (GJ)	8328	2899	0	0	-	
Total Actual Energy Usage (GJ)	13795	11352	7350	6066	15876*	
Gross Floor Area (m ²)	3703	11714	6083	9624	18460	
Actual Energy Intensity (GJ/m ²)	3.73	0.97	1.21	0.63	0.86	

Table 4: Annual Energy Consumption & Energy Intensity

* This value was calculated by multiplying the AEI by the GFA as the energy usage was not provided

While it may be tempting to use the data from Table 4 above to simply compare the energy usage or energy intensity of each building to draw the conclusion that one (1) is outperforming the rest, this may result in an unfair comparison. Although these buildings have been preselected for this study due to similarities in building type, location and time period, it is important to consider key (energy-affecting) variables such as climatic region, building size, building type, process loads, and occupancy schedules as outlined in Chapter 1 and Chapter 3. To illustrate this point, when comparing the actual energy usage of the buildings in this research, the Stevenson-Lawson Hall consumes far more (almost twice as much) energy than Simcoe Hall, however the energy intensity of the Stevenson-Lawson Hall is far less. As indicated by this example, assessing the energy consumption of these five (5) buildings without taking into context their GFAs would be an unfair comparison. When the energy intensity of the buildings was compared, it was determined that the Claudette MacKay Lassonde Pavilion consumed far more energy than the rest of the buildings in this study. This building had the highest annual energy usage and the smallest gross floor area, resulting in an energy intensity of almost four (4) times greater (3.73 GJ/m^2) than the average of the other buildings (0.89 GJ/m^2).

Although the central focus of this study is to determine how LEED buildings are performing, the data will inevitably raise the question of why some buildings perform better than others. In regards to the significantly higher energy intensity of the Claudette MacKay Lassonde Pavilion compared to the other four (4) buildings in this study, it was observed that this building "houses collaborative learning, graduate student educational facilities and office spaces for professors.

Two floors of the building house engineering laboratories for leading-edge environmental research" (Enermodal Engineering, 2014, Executive Summary). It is well understood that laboratory spaces with energy-intensive equipment can greatly increase the process-related internal loads and thus overall energy consumption of a building. This is one (1) likely reason why the actual energy intensity of the Claudette MacKay Lassonde Pavilion was much greater than that of the other buildings being studied. This observation highlights the inequity of comparing academic buildings with extremely large process loads, such as engineering laboratory spaces, to academic buildings used predominately for office spaces/lecture halls. Table 2 and Table 3 identify the different uses of each of the buildings analyzed in this study.

4.2 How LEED certified buildings compare to existing Canadian energy benchmarks

Currently, there are five (5) relevant energy surveys available in Canada which provide the average energy intensity of all buildings studied per building type – the CIBEUS 2000, CES 2003, CICES 2005, CICES 2008 and SCIEU 2009. As discussed in detail in Chapter 2, each survey was conducted by Natural Resources Canada and Statistics Canada to provide national, regional and building usage specific energy intensities to "establish baseline energy consumption figures" (Natural Resources Canada, 2012, p. I) against which commercial and institutional buildings are often compared.

The energy intensities for each of the buildings participating in this study were compared to all five (5) energy surveys to further categorize their overall energy performance. A summary of

the building energy intensities as well as each survey's average energy intensity is shown in Table 5 below.

	Building							
	Claudette MacKay Lassonde Pavilion	Stevenson-Lawson Hall	Simcoe Hall	Ron Joyce Centre	ACCE			
Actual Energy Intensity (GJ/m ²)	3.73	0.97	1.21	0.63	0.86			
CIBEUS 2000 (GJ/m ²)	0.93 (universities & colleges)							
CES 2003 (GJ/m ²)	2.19 (universities); 1.35 (colleges)							
CICES 2005 (GJ/m ²)	3.12 (universities); 1.55 (colleges)							
CICES 2008 (GJ/m ²)	1.24 (universities); 0.95 (colleges)							
SCIEU 2009 (GJ/m ²)	0.97 (universities & colleges)							
BPS 2012 (GJ/m ²)	1.65 (universities); 1.15 (colleges)							

Table 5: Building & Benchmark Energy Intensities

The results show that the actual energy intensity values of LEED certified academic buildings are on average lower than the provincial average, but in some cases the buildings are performing much worse. The energy intensity of the Claudette MacKay Lassonde Pavilion is higher than every provincial energy average from 2000 to 2009 as well as the BPS 2012 average. The energy intensity of Stevenson-Lawson Hall is lower than the energy intensity targets of all of the averages except for one (1) – CIBEUS 2000. The energy intensity of Simcoe

Hall is less than the energy intensity of four (4) averages (CES 2003, CICES 2005, CICES 2008, BPS 2012), but higher than the remaining two (2) averages (CIBEUS 2000, SCIEU 2009). Both the Ron Joyce Centre and the ACCE have energy intensities far below all six (6) of the energy intensity averages.

While there are currently five (5) Canadian surveys, there are no guidelines as to which should be used. This should raise a question for academic institutions – *which survey average should be used for an energy intensity comparison?* After evaluating the categorization criteria for each study, one realizes that this is a tough question to answer as each of the surveys use different data groupings.

CIBEUS 2000 data is 15 years old and aggregates all educational-type buildings across Ontario. Given its age, it may not be the most temporally relevant comparison for current building projects nor an accurate average for buildings with strong energy/climate correlations as the data are Ontario-wide.

The CES 2003 survey is over 10 years old, but does look at specific academic building types – colleges, universities, and CEGEPS - across Canada. Although this survey is slightly more temporally relevant than the previous survey, the CES 2003 survey still only provides provincial energy intensity averages, rather than more localized climatic regions. These data may therefore be applicable for academic buildings in Ontario whose energy is not strongly affected by weather.

Similar to the CES 2003 data, both the CICES 2005 and CICES 2008 surveys provide energy intensity averages for universities and colleges across Ontario. These surveys provide more temporally relevant data than the two (2) previous surveys as they are both less than 10 years old. CICES 2005 and CICES 2008 also both provide provincial-level data and are not region specific. There is large variability between the energy intensity values for the CICES 2005 (3.12 GJ/m²) and CICES 2008 (1.24 GJ/m²) surveys. This may be due to the fact that more universities provided data for their buildings in the CICES 2008 survey, but the exact reasoning could not be obtained from NRCan.

The SCIEU 2009 survey is the most temporally relevant survey completed, but unlike the rest of the surveys conducted, it aggregates colleges and universities into an "other" category which includes "entertainment, leisure and recreation buildings (arenas), [and] shopping centres" (NRCan, 2012, p. 115). The SCIEU 2009 characterizes the building data using different climate zones instead of aggregating the data by province. All of the buildings analyzed in this study fall into the "Great Lakes/St. Lawrence" climate zone. While the addition of more climate zones is valuable for buildings whose energy use is strongly affected by climate, by aggregating many building types into one category, the relevance of the data is significantly diminished. Table 6 contains a summary of several attributes of the NRCan building energy surveys.

Table 6: Summary of NRCan Surveys

Survey	Temporal Relevance	Building Category By Usage Type	Provincial Data	Regional Sensitivity
CIBEUS 2000			Х	
CES 2003		х	Х	
CICES 2005	X	х	х	
CICES 2008	х	х	х	
SCIEU 2009	Х			Х

In discussions with energy practitioners and from the author's personal experience none of these surveys are very useful – the climate regions, temporal data, or building use types all vary, as do the results from one study to the next. Having evaluated the energy surveys, one can conclude that they do not seem to provide a clear energy average or benchmark (as used in the industry to mean a comparison value) necessary for an "apples-to-apples" comparison for academic buildings in Ontario.

Out of all the different categorization factors used by the study, the one (1) factor expected to have the greatest impact on energy intensity for academic buildings is the building usage type; an average that references the same building type as the one being studied is imperative. Climate can also play a role in the energy intensity of a building but this may not prove to be a large factor in lecture/hall buildings as per the BPS 2012 data analysis performed. As the majority of the current surveys are separated primarily by province and the HDDs and CDDs days across Ontario do not fluctuate drastically (with the exception of extreme northern buildings), the energy intensity associated with climate should be similar in the averages provided. A large concern for future energy benchmarks and energy surveys for academic buildings is the fluctuation in process loads depending on what mix of uses it houses. Process loads can drastically change the energy usage of a space and have not been captured in any of the surveys to date.

Although none of the current energy surveys are very accurate for academic buildings to use as for apples-to-apples energy intensity comparison, there needs to be some basis of comparison for energy usage in order for building owners to determine a baseline energy standard for new buildings or retrofits. Some campuses use the government energy surveys, others use their campus-wide energy intensity, and some hire energy consultants to determine a suitable energy intensity. The government energy surveys as well as the future published BPS data should be used as a preliminary starting point for new buildings, then utilizing internal campuswide energy intensities, and, if the budget allows, an energy consultant can be hired to make recommendations based on similar buildings and new technologies.

Based on the aforementioned observations, if a single NRCan energy survey needed to be selected for the basis of comparison, the CICES 2008 data would be the survey of choice. This survey provides energy intensity averages for both colleges and universities provincially and has temporally relevant data. Furthermore, in discussions with building energy professionals, the energy intensities for academic buildings from this survey are considered to be more realistic than the intensity values from the other surveys.

The Ontario public building data (BPS data) provided due to the implementation of the Green Energy Act has created an opportunity to generate a new provincial or even regionally specific average. The current BPS 2012 data were analyzed to determine how the case study buildings performed in comparison to other universities and colleges throughout Ontario. The data statistics and frequency trends of BPS 2012 are shown in Figure 3 and Table 7 below:

Table 7: BPS 2012 Data Results

	Min	Median	Mean	Max	Standard
	(GJ/m²)	(GJ/m²)	(GJ/m ²)	(GJ/m ²)	Deviation
BPS 2012	0.01	1.04	1.49 [*]	14.34	1.00

*The mean is calculated using the GFA method – sum the total energy of all buildings and divide by the total GFA. This is consistent with the provincial energy surveys by NRCan.

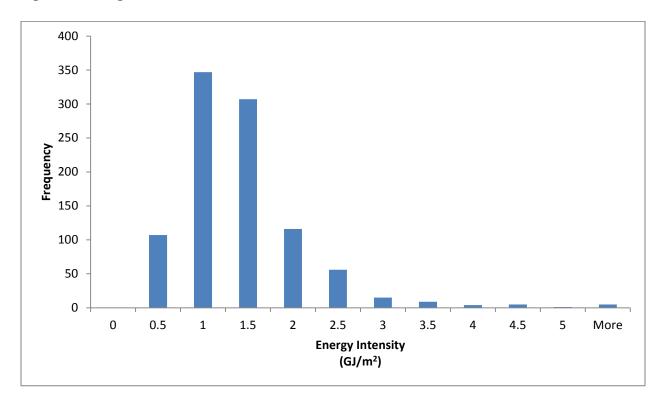

Figure 3: Histogram of BPS 2012 Data

Approximately one (1) quarter (22%) of the buildings/campuses that provided information for BPS 2012 had energy intensities between 0.75 and 1.0 GJ/m². The majority (67%) had building energy intensities between 0.51 and 1.5 GJ/m². Four (4) out of five (5) of the buildings considered in this research – Stevenson Lawson Hall, Simcoe Hall, Ron Joyce Centre and the ACCE – perform within this range of energy intensity. The Claudette MacKay Lassonde Pavilion, with a much higher energy intensity of 3.73 GJ/m², performs similarly to the highest intensity 0.4% of the BPS 2012 buildings. This analysis show that the case study buildings used in this research perform similarly to other colleges and university buildings across Ontario.

Quality of the BPS 2012 data is poor. There are missing or invalid entries, variation between reported units, buildings/facilities that did not take part, and minimal data quality assessment (duplicate entries were removed). Additionally, there is no mention as to what the Ministry of Energy will do to assure data quality or whether there are plans to utilize these data beyond publishing them.

Academic decision makers can use these publicly available data in conjunction with the government energy surveys when constructing new buildings and setting their own internal campus energy targets, but with caution. Both NRCan and the Ministry of Energy need to make changes to their programs (consistency, methodology, and data quality) to create better energy surveys for academic institutions. If academic decision makers choose to use these values for comparison, it is recommended that more than one (1) data source be used. For example, the average of the 2012 energy data for all 'Post-Secondary Educational Institute' buildings

(including both universities and colleges) was found to be 1.49 GJ/m². Dividing this further showed the average energy intensity for universities in Ontario was 1.65 GJ/m² and for colleges in Ontario was 1.15 GJ/m². Comparing the BPS data with the provincial energy surveys and then to the energy performance of similar buildings on campus will give academic decision makers an indication of the range of energy intensities that new buildings should have. While the provincial and BPS 2012 averages are recommended to use as a starting point for setting internal energy targets, these averages are a snapshot of how academic buildings are currently performing. It is recommended that future buildings push the envelope and strive to construct and operate buildings that have better energy intensities than the current working averages and realised energy intensity of similar campus buildings.

4.3 How dataset buildings compare to campus-specific energy performance

The aim of this research was also to show how LEED certified academic buildings were performing in comparison to their campus-specific energy intensities. For each of the studied buildings, annual average energy intensity values were calculated in Table 4.

The results for both the building specific energy intensity and campus-wide energy intensity in units of GJ/m^2 are shown in Table 8 below.

		Build	ing/Campus		
	Claudette MacKay Lassonde Pavilion (Western)	Stevenson- Lawson Hall (Western)	Simcoe Hall (Lakehead)	Ron Joyce Centre (McMaster)	ACCE (Algonquin)
Building Energy Intensity (GJ/m ²)	3.73	0.97	1.21	0.63	0.86
Campus-wide Energy Intensity (GJ/m ²)	1.91	1.91	1.16	1.77	1.14

Table 8: Energy Intensities Compared to Campus-wide Energy Intensities	Table 8: Energy Inte	nsities Compare	d to Campus-wide	Energy Intensities
--	----------------------	-----------------	------------------	--------------------

The results indicate that three (3) of the five (5) buildings in this research consume less energy than their associated campus-wide average. The actual energy intensity of the Claudette MacKay Lassonde Pavilion at 3.73 GJ/m² grossly exceeded the Western University campus-wide energy intensity value of 1.91 GJ/m². Similarly the energy performance of Simcoe Hall exceeded Lakehead University's campus-wide energy intensity by a small margin of 0.05 GJ/m². Stevenson-Lawson Hall, the Ron Joyce Centre, and the ACCE all performed much better than their associated campus-wide energy intensities.

At Western University in London, Ontario 12 out of the 90 buildings on campus are either LEED certified or in the process of applying for LEED certification. From the information provided there is no way to accurately separate the energy usage for the LEED and non-LEED buildings. Therefore, based only on the number of LEED versus non-LEED buildings, approximately 87% of the buildings would be considered non-LEED equivalents for comparison purposes. From the results shown above the Claudette MacKay Lassonde Pavilion performs far worse (consuming almost twice as much as the WU campus-wide energy intensity) than its LEED and non-LEED and

campus counterparts. On the other hand, Stevenson-Lawson Hall performs much better (consuming almost half as much as the WU wide energy intensity) than both its LEED and non-LEED campus counterparts. In so far as examining whether LEED buildings are performing better than non-LEED buildings, the data for these two (2) buildings present conflicting results. Based solely on the results of the two (2) aforementioned LEED buildings at Western University, it cannot be concluded with certainty that LEED buildings are performing better in comparison to other buildings on campus. It is recommended that future LEED buildings be monitored for energy performance in order to help understand how LEED buildings are performing at this campus.

At McMaster University, the Ron Joyce Centre is consuming only 36% of the campus-wide energy intensity of 1.77 GJ/m². Approximately 25% (12 out of the 48 buildings) of the building stock at McMaster University are LEED certified due to their sustainable building policy which "states that every new building on campus will have a minimum of Leadership in Energy and Environmental Design (LEED) Silver Certification. The return on the LEED investment includes financial and energy savings and increased efficiency in utilities and other operating costs over the building's lifespan" (McMaster, 2011). With McMaster's performance of the Ron Joyce Centre and through discussions with their energy department, LEED buildings on this campus are out-performing the non-LEED buildings at this campus.

Simcoe Hall at Lakehead University in Orillia saw slightly elevated actual energy intensity (at 104%) in comparison with its campus-wide energy intensity. All three (3) buildings currently

constructed the Lakehead University campus in Orillia are LEED certified and therefore a comparison between LEED and non-LEED buildings cannot be made.

The ACCE building at Algonquin College is outperforming the campus-wide energy intensity by 31%. The ACCE building is one (1) of two (2) LEED certified buildings at the Algonquin College Woodroffe Campus and as such it is fair to say that this LEED certified building is outperforming the rest of the non-LEED buildings on campus. Additionally, in 2014 the Physical Resources team at Algonquin College published a "Post Occupancy and Thermal Comfort Analysis: ACCE Building – Final Report" document which demonstrated the energy intensity comparisons between the LEED and non-LEED buildings. The average energy intensity for both of the LEED certified buildings on campus are 32% better than the non-LEED campus-wide energy intensity in the same year.

4.4 How dataset building actual energy intensity compared to the LEED energy models

Another aim of this research was to show how LEED certified academic buildings were performing in comparison to the modelled energy consumption (energy numbers provided for final LEED certification). Each of the universities in this study provided their final LEED Letter Template for the Energy and Atmosphere Credit 1: Optimize Energy Performance (EAc1) which summarizes the final energy modeling results submitted to the CaGBC. The EAc1 Letter Template lists the building's modeled energy usage broken out by end use (e.g. lighting or fans) and energy source (e.g. electricity or gas). The energy usage values from the LEED EAc1 Letter Templates were converted to GJ and then divided by the corresponding building's GFA to

calculate the modelled energy intensity. The modelled energy intensities were then compared to the actual energy intensity of each building. The results are shown below in Table 9 below.

	Building				
	Claudette MacKay Lassonde Pavilion	Stevenson-Lawson Hall	Simcoe Hall	Ron Joyce Centre	ACCE
Actual Energy Intensity (AEI) (GJ/m ²)	3.73	0.97	1.21	0.63	0.86
Modelled Energy Intensity (MEI) (GJ/m ²)	2.10	0.74	0.68	0.62	0.55
Discrepancy: 100% - (MEI/AEI)	44%	24%	44%	2%	35%

Table 9: Annual Energy Intensity and Modelled Energy Intensity

The results demonstrate that all of the modelled energy intensities were lower than the actual building energy intensities. As mentioned in Chapter 2, the predicted energy use intensities (EUI) for the simulated buildings often deviate from the actual measured energy use by large amounts, ranging from 14% to 41%. The modelled energy intensities of the buildings in this study deviated from actual energy intensities in the best case by 2% (for the Ron Joyce Centre) to the worst case of 44% (for both Simcoe Hall and the Claudette MacKay Lassonde Pavilion). The findings of this research are in agreement with current academic research where the modelled energy use of buildings do not in general reflect the actual energy usage of a building (models typically under predict actual energy use).

4.5 How does this research affect academic building owners and operators?

It is a common misconception that a LEED energy model accurately reflects the future energy usage of a building. Owners and operators generally think that the modeled energy savings documented on the EAc1 Letter Template will equate to realized energy savings demonstrated on utility bills. Research has shown this is not often the case. The documentation for LEED EAc1 requires a computer simulated model to be compared to a similar baseline building which meets the requirements and guidelines outlined by the CaGBC (and their reference modeling standards). As such, a percentage of savings can be determined by comparing these two (2) values – proposed building to reference building (baseline). The percent savings calculated in this process does not accurately demonstrate cost savings realized by an owner. From personal experience, this information typically does not seem to be properly conveyed to the owners and operators of a building who tend to expect a significant decrease to their overall energy consumption based on the modeled savings.

This study demonstrates the energy savings associated with LEED certification of academic buildings. Four (4) out of the five (5) buildings studied in this research on average perform better than the five (5) energy surveys from NRCan and Statistics Canada as well as the BPS 2012 energy intensity average. Similarly, three (3) out of the five (5) buildings performed better than their campus-wide energy intensity values.

In general, this research demonstrates that in aggregate, the group of LEED certified academic buildings selected for this study do perform better from an energy perspective than the average

provincial energy data for academic buildings in Ontario. However, each building studied in this research had higher (ranging from 2% to 44%) actual energy intensities compared to the modelled energy intensities.

Chapter 5: Conclusions and Recommendations

Based on the results presented in Chapter 4, the goal of this chapter is to draw conclusions and provide final recommendations to NRCan and Statistics Canada, the CaGBC and USGBC, the energy modelling community, and academic campus decision makers.

5.1 Conclusions

The results of this study demonstrate that these five (5) case study LEED certified academic buildings do, in fact, on average have overall lower energy intensities compared to the provincial energy intensity averages for academic buildings in Ontario. While the goal of this study was to determine if LEED buildings performed better than non-LEED buildings, there were not enough case study buildings (or appropriate non-LEED building data) available to definitively answer this question.

At Western University, the Claudette MacKay Lassonde Pavilion performed anywhere from 16% to 75% worse than the provincial average energy intensities. Stevenson-Lawson Hall, on the other hand, ranged from 4% worse than one (1) average (CIBEUS 2000) to 69% better than another (CICES 2005). At Lakehead University, Simcoe Hall performed 23% worse when compared to CIBEUS 2000 and up to 61% better than three (3) of the provincial averages. The Ron Joyce Centre at McMaster University performed anywhere from 32% to 80% better than the provincial averages. Lastly, the ACCE building at Algonquin College performed between 8% and 45% better than the provincial averages.

This research demonstrates that there is a diverse and sometimes conflicting range of provincial energy intensity data provided by NRCan and Statistics Canada which makes it impossible for academic institutions to make educated and useful decisions on energy intensities of campus buildings. Without guidance on which energy survey to use, it is extremely difficult to determine how an academic building is performing in comparison to its provincial counterparts. By publishing inconsistent data with changing aggregation categories including both building types and location, NRCan and Statistics Canada are creating confusion about how a building is actually performing as practitioners could use different surveys to portray the building's energy performance. This leads to inconsistencies in reporting relative building performance and can lead to gamesmanship.

The annual public reporting mandated for public buildings in Ontario due to the Green Energy Act has provided practitioners with data for other potential comparison, but the quality of these data at present is poor. The data quality and measurement needs to be standardized in order for these data to be used. Currently, public institutions provide metrics such as GFA and energy data in varying units which makes it nearly impossible to analyze thousands of entries of inconsistent data. Additionally, there appears to be issues with some of the data that public institutions are reporting as some entries are absent or unexpectedly low, if not impossible, values. Some form of quality assurance needs to take place to ensure that institutions are accurately reporting the performance of their buildings and some form of accountability needs to be put into place. There is no value in reporting such data, should it be inaccurate and unusable by others. On average, the buildings in this research do perform better from an energy perspective than the campus-wide energy intensities. The results of this study show demonstrate that 60% (three (3) out of the five (5)) buildings perform better than their associated campus-wide energy intensity. The Claudette MacKay Lassonde Pavilion performed 49% worse than the campus-wide energy intensity at Western University while the Stevenson-Lawson Hall performed 49% better. Simcoe Hall performed 4% worse than the campus-wide energy intensity at Lakehead University and the Ron Joyce Centre performed 64% better than the campus-wide energy intensity at McMaster University. The ACCE building performed 31% better than the campus-wide energy intensity at Algonquin College. These results demonstrate that these LEED buildings do in-fact aid in decreasing the overall energy usage of buildings on campus.

Each building studied in this research had higher actual energy intensities (ranging from 2% to 44%) when compared to the modelled energy intensities for LEED certification. These findings seem to be consistent with current academic literature (discussed in Chapter 2) which lists deviations from the actual measured energy use on average ranges from 14% to 41%. The energy model for the Ron Joyce Centre was the most accurate simulation with a 2% discrepancy between the modeled and actual energy intensity. The discrepancy between the actual energy intensity for Stevenson-Lawson Hall was 24% and the ACCE building was 35%. The discrepancies were much larger for both the Claudette MacKay Lassonde Pavilion and Simcoe Hall at 44%. These large discrepancies demonstrate that the energy model

created for LEED demonstration purposes is not an accurate reflection of how a building will be performing from an energy perspective. In order to achieve points in a rating system, buildings should be rewarded based on actual energy savings and as such if these models are not an accurate reflection of the building they should not be solely used to demonstrate compliance.

5.2 Recommendations

Based on the conclusions of this study, and as an experienced LEED practitioner, recommendations to NRCan and Statistics Canada, the CaGBC and USGBC, LEED energy modellers and academic campus decisions makers will be provided in this section. The goal of these recommendations is to improve the overall process of integrating LEED buildings into academic campuses and also to improve the predicted performance of LEED energy models for these associated buildings.

5.2.1 Recommendations for the Ministry of Energy, NRCan and Statistics Canada

The results of this study demonstrate the need for NRCan and Statistics Canada to provide more relevant energy surveys for academic buildings. The existing energy intensity surveys relevant to academic buildings provide multiple years of data with varying building-type categories, building ages, and geographical catchment areas; as a result, the studies do not provide a good basis of comparison for academic buildings to use as a metric of comparison. As outlined in Chapter 4, geographic location can have an impact on the energy use (and therefore the energy intensity) of a building although the attempt in this study to demonstrate the actual difference in Ontario academic buildings was unsuccessful. Through discussion with various energy professionals, provincial data should provide valid climatic information for utilization in an energy benchmark (instead of using location specific benchmarks), but more location specific data would be ideal. The SCIEU 2009, the most recent survey, does categorize the buildings in their study by climatic region, which is an improvement over the previous studies and should provide a better benchmark for buildings. It is therefore recommended that going forward the commercial and institutional surveys should continue this climatic categorization.

Unfortunately, the SCIEU 2009 survey aggregates academic buildings into an 'other' category along with recreational buildings and shopping centres. This severely dilutes the validity and usefulness of this information to academic decision makers. It is therefore recommended that future surveys conducted by NRCan and Statistics Canada break down the 'other' category specifically for each building use type - universities, colleges, and CEGEPs - as did the CICES 2005 and CICES 2008 surveys. By using relevant climatic regions and breaking down the 'other' category into building usage types, this would allow for academic institutions to make better decisions regarding their energy intensity targets and use this information as a baseline metric against which to compare.

Another drawback of the current energy surveys is the lack of building age data for the different building types. While some of the surveys (CIBEUS 2000, CICES 2005, and CICES 2008) have reported the average energy intensity value of buildings for various years of construction, without building type information these averages are of minimal use. It is not very useful to compare a new academic building against the average academic building in Ontario when existing buildings are of varying ages which means different construction quality and building performance. The ideal benchmark would have geographical, building use type, and age criteria for the most useful comparison as a new building should aim to be better than the current state of construction, not the average over the past 100 years.

It should also be noted that there is no differentiation in the benchmarks between academic facilities which utilize high process load spaces such as laboratories and those that do not. It is recommended that future studies separate high process load buildings such as engineering lab facilities versus lower load buildings such as classrooms. Process loads play a large role in increased energy usage and therefore benchmarks need to somehow incorporate these differences.

In addition, it is recommended that a user's guide be provided to help guide those using the surveys to ensure fair 'apples-to-apples' comparisons can be made.

The annual reporting that is mandated due to the Green Energy Act needs to be standardized and upheld. Currently public institutions are reporting data in varying units, inconsistent entries, and skewed values. There needs to be some sort of data quality check in place to ensure that all data reported is accurate. Should the quality of this data be improved, it could be used by researchers to create new energy intensity comparisons (provincial averages, geographically relevant, superior performance target, etcetera) for various building types.

5.2.2 Recommendations for the CaGBC and USGBC

The results of this study demonstrate that these specific LEED certified academic buildings have, on average, lower energy intensities when compared to the average energy intensity of academic buildings in Ontario. While in aggregate there seem to be energy benefits in obtaining LEED certification, there are still LEED certified buildings that are performing significantly worse than the provincial average. The LEED rating system is a certification which boasts that a building will "save money and resources and have a positive impact on the health of occupants, while promoting renewable, clean energy" (USGBC, 2015). Yet, in some instances, it has been shown that buildings that have received certification are, in fact, performing worse than the provincial averages as well as the campus-wide energy intensity. There needs to be some form of accountability and enforcement put into place by the CaGBC and USGBC to ensure these buildings operate and perform as intended.

Additionally, there are obvious issues with the achievement and documentation of LEED energy points. The current academic literature and the results of this study show that there are discrepancies between the LEED energy model and actual energy use ranging anywhere from 2% in the most accurate models to 44% in the least accurate models. Personal experience with energy modelling and M&V data has shown model discrepancies in some instances much larger than 44%. While it is understood within the energy modelling community that LEED models are not necessarily predictive of actual energy use, but rather demonstrate relative savings compared to a baseline building. In this paradigm however, the model provides very little benefit other than documenting LEED energy points. As a result, there is little benefit to the owners of such buildings when the results shown do not reflect their actual buildings. There is currently no reconciliation between the demonstrated savings for LEED certification and the actual usage of the building post-occupancy. If the energy models are significantly different than actual usage it is the author's personal opinion that a building should not be awarded LEED points for theoretical and not realizable savings. Instead, one (1) recommendation would be to implement a one (1) year period of post-occupancy analysis whereby the M&V data is used to calibrate the simulation and provide updated energy savings to document and award LEED points. Within the current LEED paradigm, there are tangible rewards and therefore pressure to demonstrate a high percentage of savings in order to gain a large number of energy-related LEED points. There is nothing in place to ensure the model accurately reflects the true building operation. This disconnect, which is inherent to the process, requires an additional level of energy accountability which should be mandated through the CaGBC and USGBC (such as financial or point related impacts for inaccuracies).

This research has demonstrated that obtaining information from building owners and operators post-LEED certification is an extremely difficult process and that often times these individuals had negative feelings towards the LEED process. Building owners refused to take part in this study for various reasons, but one particularly problematic issue was the unsuccessful implementation of plans and systems necessary for the LEED M&V credit. This may be due to improper metre sizing, a lack of following through with the M&V plans, data not correctly being reported from the M&V consultant/host server to the building owner, or even a change of operating staff. Whatever the reason, M&V is an extremely useful tool that should be utilized by building owners and operators, but its value is often unrealised (even when owners have paid the additional costs associated). Energy modelling and performance based incentives are being utilized more in the industry, and CaGBC and USGBC should ensure that the M&V requirements are properly completed before granting this credit. Placing accountability on the actual performance of a building will reduce some of the negative feelings attributed to LEED.

From both professional experience and through trying to obtain data from universities in this research it was found that often there is a disconnect between the LEED certification process and the operation of the building – there is no physical hand-off of the LEED documentation, M&V plans, commissioning plans, etcetera to the owners and operators of the building. When someone then requests this additional information about the building – the owner frequently has no idea where to look and often requesting this data from the LEED consultant results in additional costs. There should be a way for building owners to request data from the CaGBC, or else the implementation of a program similar to LEED Online (in the US) where the uploaded documents (including energy information in the EnergyStar Portfolio Manager) are centrally stored and accessible by future users.

As a practitioner in this field of sustainability and energy efficiency, the negative stigma associated with the process of LEED certification and the hand-off to building owners and operators is concerning and could drastically impact the future of the LEED program in Canada.

5.2.3 Recommendations for the LEED energy modeller

As mentioned in the previous section (recommendations for the CaGBC and USGBC), there needs to be increased accountability for the results of LEED energy models. Through discussions with energy modeling professionals, there appears to be a perception that LEED models do not need to be as accurate as models for other applications, for example Ontario Building Code (OBC) and Public – Private Partnerships (P3) projects, where reflecting actual building energy usage is deemed more important. It is the author's opinion that it is the duty of the modeller to ensure that each model is as accurate as possible (within the confines and rules of the regulating program), and that modellers are exercising their due diligence to provide the owner with a simulation that attempts to reflect actual building operation. "There are many reasons why buildings do not perform as modeled, for example, change in design and construction, as well as operation and maintenance issues that can all affect the energy use of the actual building" (Diamond, 2011, pg. 2). While there is no way to simulate a building 100% accurately, there are ways to ensure the energy model is more reflective of reality – calibrated simulations, M&V, checking all shop drawings, discussing operating conditions with the owner and designers. One large systematic obstacle for the energy modeling community is that after a project achieves certification, there is no follow up on the project - unless the project is pursuing the M&V credit. This lack of feedback promulgates the disconnect between the theoretical model and the actual building operation – whereby the actual building operation is in no way connected to the modeling procedure. It is therefore recommended to the CaGBC and USGBC to provide more compelling incentives to increase the accuracy of the energy models and place a higher level of accountability on energy modellers. For their part,

professional energy modellers need to raise their level of accountability in order to provide the best model possible for their clients and to help raise the stature of the LEED program.

5.2.4 Recommendations for academic campus decision makers

Gains achieved with energy efficiency can help provide savings in order to achieve better financial paybacks as it relates to LEED certification. While LEED is perceived by some to be an expensive process, this study has shown that these case study LEED certified academic buildings are achieving energy savings when compared to both provincial average and campus-wide energy intensities. It has been observed, however, that not all LEED certified buildings are performing as intended nor as well as the modeled energy predictions. It is the author's opinion there is great potential for a LEED building to perform much better from an energy perspective than non-LEED equivalent buildings, but it is the responsibility of the designers, the commissioning agents, M&V consultants and operators to ensure the building is designed and operated to its full potential to ensure these savings are achieved.

Often on new LEED projects key decision makers, staff committees, designers, and LEED consultants take part during the design and certification phases. But, unfortunately, many times operators of the building are left out of these design discussions and are not told how the building would ideally be operated to maintain energy efficiencies. It is recommended that the building operators are brought into the design discussions early in the process to create synergies between how operators would like to run the building at the campus and implementing new technologies or systems that would aid in energy efficiency. In the author's

professional experience that too often these discussions do not occur and the operation teams do not agree with the new technologies implemented. This leads to many headaches associated with the operation and maintenance of the new building and an overall negative feeling by operation staff towards the entire LEED system. It is possible for a building to achieve LEED certification, but with M&V systems that are unable to provide data because the building is not working as designed (i.e., metres are sized incorrectly and are not reporting valid or accurate data). When the building operation staff and owners of the building are aware of the M&V process and have ideas of how the M&V data will be used in the future (through postoccupancy analysis or to provide to researchers), then it is more likely there will be follow ups to ensure that all systems are constructed properly within warranty periods.

Commissioning as well as M&V are also very important steps that should take part in the construction and maintenance of new buildings. Commissioning helps to ensure that all systems are running properly and as designed; whereas, M&V helps to ensure that systems are running effectively or aids in troubleshooting issues that arise. Both of these steps aid in ensuring that the new building is running as smoothly as possible while giving operators feedback on items that require improvement. If these two (2) steps happened on each and every new building the quality and efficiency of new buildings would be significantly increased.

Academic decision makers also need to understand that the savings calculated by the LEED energy model do not equate to the overall energy savings that will be realized. While most energy modellers attempt to accurately model a building, there will always be differences in construction materials used, occupant usage, and how the building is operated, which will result in discrepancies. To reduce the discrepancies, it is recommended to include the building operators in the design process in order to provide a better understanding of how the building will actually be operated; this is of benefit to the energy modeller and LEED consultant and will help ensure the energy model is as accurate as possible. It is also critical that energy modellers receive better information on equipment that consumes a large amount of energy – such as laboratory equipment and server rooms. These loads, along with their anticipated operating schedules, need to be conveyed to the energy modeller. By providing better information relating to these large sources of energy usage, the models will more accurately reflect the building.

Energy intensity comparisons such as energy surveys and the BPS data (specific to building use type and geographical location) should become part of the design process. Relevant comparisons should be discussed with designers and considerations should be made in regards to achieving better energy intensity values for the new buildings. Due to recent legislation (Green Energy Act (Ministry of Energy, 2015)), each Ontario academic campus now has its own published annual average energy intensity comparison which could be used for benchmarking and goal setting. For buildings pursuing LEED certification, it is recommended that academic campus decision makers require that new buildings achieve significantly lower energy intensities than non-LEED equivalent buildings of the same building type, age, and climatic region. The government supplied energy surveys as well as the specific campus-wide energy intensity provide some indication of how the average academic building is performing, but are not a good indication of how a new LEED building should perform. In order to uphold the principles of the program, a new LEED building should provide superior environmental (including energy) and human health advantages in comparison to non-LEED equivalent buildings – this should be the responsibility of the entire design team and building operators as well as the academic decision makers.

5.3 Recommendations for future research

Due to a limited sample size, this research was limited to the study of only a handful of LEED NC v1 certified academic buildings in Ontario. Future research, when more LEED academic buildings are certified and have M&V data available, is recommended to build upon this research. It would also be of interest to determine how LEED v2009 and LEED v4 buildings are performing in comparison to the provincial energy surveys, campus-wide energy intensities, and the LEED energy models.

It is also recommended that future research be conducted on the quality of energy surveys and potential energy benchmarking across Canada. Ideally, a framework will be created and implemented by the government to create an accurate academic energy benchmark which also accounts for process loads of different building types.

Additional research is also needed to determine how energy models can better reflect actual building energy use. There is currently very little academic literature addressing topics related to energy modelling which is problematic as it is becoming a large industry with very little guidance and expertise. It is therefore recommended that more energy professionals share their knowledge and experience through publications in order to decrease the variability between modeled energy and true energy usage.

Appendix A: LEED Rating System Categories and Points

LEED CREDIT	POINTS				
Sustainable Sites (14 Points)					
SSp1: Erosion and Sedimentation Control	None				
SSc1: Site Selection	1				
SSc2: Development Density	1				
SSc3: Redevelopment of a Contaminated Site	1				
SSc4: Alternative Transportation					
SSc4.1: Public Transportation Access	1				
SSc4.2: Bicycle Storage and Change Rooms	1				
SSc4.3: Alterative Fuel Vehicles	1				
SSc4.4: Parking Capacity	1				
SSc5: Reduced Site Disturbance					
SSc5.1: Protect or Restore Open Space	1				
SSc5.2: Development Footprint	1				
SSc6: Stormwater Management					
SSc6.1: Rate and Quantity	1				
SSc6.2: Treatment	1				
SSc7: Heat Island Effect					
SSc7.1: Non-Roof	1				
SSc7.2: Roof	1				
SSc8: Light Pollution Reduction	1				
Water Efficiency (5 Points)					
WEc1: Water Efficient Landscaping					
WEc1.1: Reduce by 50%	1				
WEc1.2: No Potable Use or No Irrigation	1				
WEc2: Innovative Wastewater Technologies	1				
WEc3: Water Use Reduction					
WEc3.1: 20% Reduction	1				
WEc3.2: 30% Reduction	1				
Energy and Atmosphere (17 Points)					
EAp1: Fundamental Building Systems Commissioning	None				
EAp2: Minimum Energy Performance	None				
EAp3: CFC Reduction in HVAC&R Equipment & Elimination of Halons	None				
EAc1: Optimize Energy Performance	1-10				
EAc2: Renewable Energy	1-3				
EAc3: Best Practice Commissioning	1				
EAc4: Elimination of HCFCs	1				
EAc5: Measurement and Verification	1				
EAc6: Green Power	1				

Materials and Resources (14 Points)				
MRp1: Storage and Collection of Recyclables	None			
MRc1: Building Reuse				
MRc1.1: Maintain 75% Existing Walls, Floors and Roof	1			
MRc1.2: Maintain 95% Existing Walls, Floors and Roof	1			
MRc1.3: Maintain 50% of Interior Non-Structural Elements	1			
MRc2: Construction Waste Management

Project Description

Addition to the University of Western Ontario's Spencer Engineering Building.

Project Description

A new academic building that will include classroom, lecture, lab, administrative and office spaces.

Ron Joyce Centre, McMaster University | Project 12213

4350 South Service Road, Burlington, Ontario

Certification Level: Gold

Rating System: LEED Canada for New Construction and Major Renovations 1.0

View Project Scorecard (PDF) »

Project Description

The renovation project will contain a combination of office space, classrooms, lecture halls, computer labs, and other mixed uses. This building is pursuing LEED Silver certification.

Additional Project Details

Certifying Organization:	CaGBC
Registration D	ate: 2009-02-03

Project Size (m	2): 11714
Project Type:	Lecture Hall / Classroom
Owner Type:	University / College

Project Description

McMaster University's newest development is a four storey business school for advanced management studies in Burlington, Ontario. The building's GFA is 8645m2 and is going to include classrooms, lecture halls, an auditorium, and various mixed use spaces.

Building features: - efficient envelope and HVAC system - low flow fixtures - full cut off exterior lighting fixtures - low VOC products to be used

Thumbnails

Project Description

The construction industry and Algonquin College have come together to realize this vision, taking a leadership position to create a centre of choice for construction-related educational and training needs, and bringing under one creative and collaborative cluster professional disciplines in the construction industry including architecture, interior design, engineering technology, and building trades.

The Centre will create an environment where innovation can flourish through applied research, experiential learning, shared best industry practices and business experiences. Such capacity will allow the industry, academic staff and students from various construction-related disciplines to work together to develop innovative solutions to emerging built environment problems by fostering applied research in the areas of new materials use, new techniques or methods, new applications.

The Centre will be an Integrated Learning Centre fostering inter-professional collaboration, cross-curricular design that is current and relevant, and a socially conscious environmental approach to the academic programming and delivery. Modularity, flexibility and openness of design of the labs and workshops will offer unique cross-training opportunities that will significantly enhance the theoretical knowledge and practical skills of the graduates. This would compel program disciplines to understand and appreciate their role in the bigger picture, as well as that of other disciplines involved in the same team charged with achieving the overall construction building goals.
